

QTL mapping for resistance to bonamiosis in the European flat oyster *Ostrea edulis*

Delphine Lallias, Andy Beaumont, Chris Haley, Serge Heurtebise, Pierre Boudry and Sylvie Lapègue

Plant and Animal Genome Conference, San Diego,
California, United States

January 12-16, 2008

Context of the study

- Aquaculture production of *O. edulis*

Drastic reduction of the French production, from 20,000 tons in 1950s and 1960s to 2,000 tons nowadays

This is due to two parasitic diseases:

- Marteiliosis
- Bonamiosis

Context of the study

- Selective breeding for resistance to *Bonamia* (France and Ireland)
- First stage: production of improved oyster strains by individual selection in mass spawning populations (Naciri-Graven et al., 1998; Culloty et al. 2001)
 - Low effective population sizes (Launey et al. 2001)
 - Inbreeding depression (Naciri-Graven et al. 2000)
- Second stage: within- FS family selection

Higher survival and lower *Bonamia* prevalence (▲) of selected *versus* hybrid and wild families (Bédier et al., 2001)

Aim of the study

In this context, the establishment of a genetic linkage map will provide a foundation for the identification of Quantitative Trait Loci for resistance (or tolerance) to *Bonamia*, with the ultimate objective to implement marker-assisted selection (MAS) in *O. edulis*.

Mapping family

- 2004 : Cross between a wild oyster and a selected oyster

→ F1-S family

- 2005 : Cross between 2 F1-S oysters

Flat oysters are hermaphrodites and females brood their larvae for about 10 days

Three-generation pedigree

Bonamia challenge

5 raceways (150 l/h)

110 tested oysters / raceway

Cohabitation between artificially infected wild oysters and our F2 family

Artificially infected wild oysters

F2 family (= tested oysters)

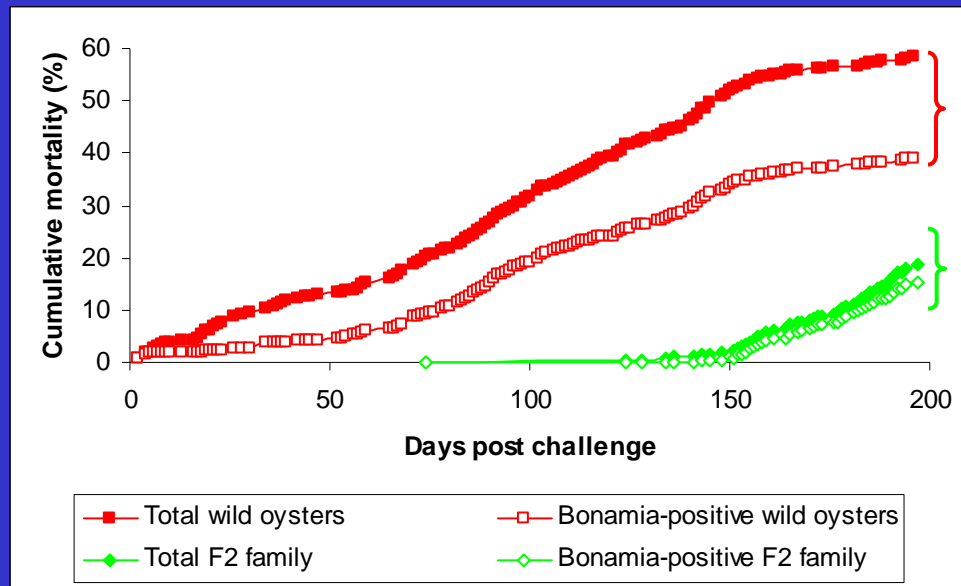

- Mortality checked daily
- Heart smears on dead oysters to search for *Bonamia*

Mortality (Jan-July 2006)

No significant raceway effect, so data were pooled between raceways

Wild oysters

Tested oysters

➤ 4 months before first infections

➤ 20% mortality in the tested oysters after 6 months

➤ scoring of 2 extreme phenotypes (microsatellites + AFLPs):

- 46 dead oysters (heavily infected)
- 46 surviving oysters (no parasite detected)

} Heart smear and PCR

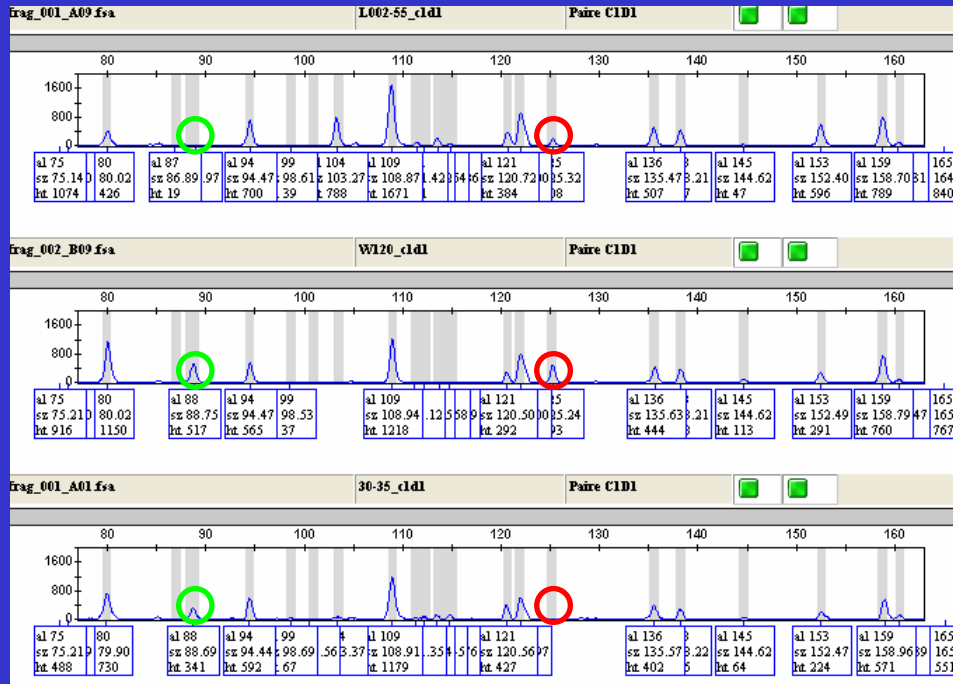

Markers and genotyping

- 20 available microsatellites
- 34 AFLPs primer pairs : 309 segregating markers in F2

Parent
410_8

Progeny
F2

ABI 3100-Avant

1:1 type (n=201)

3:1 type (n=108)

98AC703-29 x W31

410-7 x 410-8

F2 progeny

Several steps for the search of QTLs

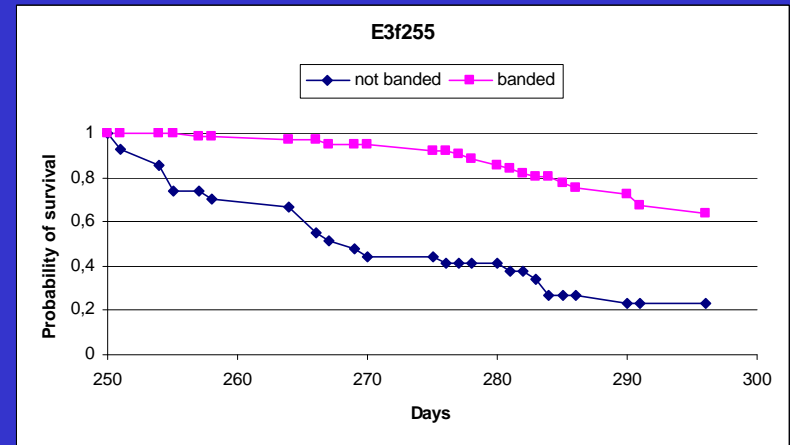

- Identification of potential markers (test marker by marker): multistage testing strategy (Moen et al. 2004)
 - Transmission disequilibrium test (TDT)
 - Mendelian Segregation Test (MST)
 - Survival analysis
- Location of those markers in the genome (genetic mapping)
- QTL mapping approach (uses genetic map and the survival data)

Multistage testing strategy (Moen et al., 2004)

309 AFLPs

6 probable susceptibility markers

9 probable resistance markers

Several steps for the search of QTLs

- Identification of potential markers (test marker by marker)
- Location of those markers in the genome (genetic mapping)
- QTL mapping approach (uses genetic map and the survival data)

Genetic mapping: CriMap (Green et al., 1990)

309 AFLPs

20 microsatellites

Parent 410_7

- 127 markers mapped
- 3 R + 1 S mapped
- 10 linkage groups
- total length: 465.6 cM
- genome coverage: 84.1%

Parent 410_8

- 98 markers mapped
- 8 R + 4 S mapped
- 10 linkage groups
- total length: 386.7 cM
- genome coverage: 69.4%

Several steps for the search of QTLs

- Identification of potential markers (test marker by marker)
- Location of those markers in the genome (genetic mapping)
- QTL mapping approach (uses genetic map and the survival data)

QTL mapping: CriMap software + QTL express

- 2 parental maps built (410_7 and 410_8): CriMap
- binary trait (death/alive)
- regression interval mapping (one-QTL model): QTL express
- large single full-sib family analysis module

Parent 410_7

- QTL1: 0 cM ($p < 0.01$), G2_410_7
- QTL2: 24 cM ($p < 0.05$), G4_410_7
- QTL3: 8 cM ($p < 0.05$), G6_410_7

Parent 410_8

- QTL1: 61 cM ($p < 0.05$), G3_410_8
- QTL2: 17 cM ($p < 0.01$), G6_410_8

G1_410_8

G2_410_8

G3_410_8

G4_410_8

G5_410_8

G6_410_8

G7_410_8

G8_410_8

G9_410_8

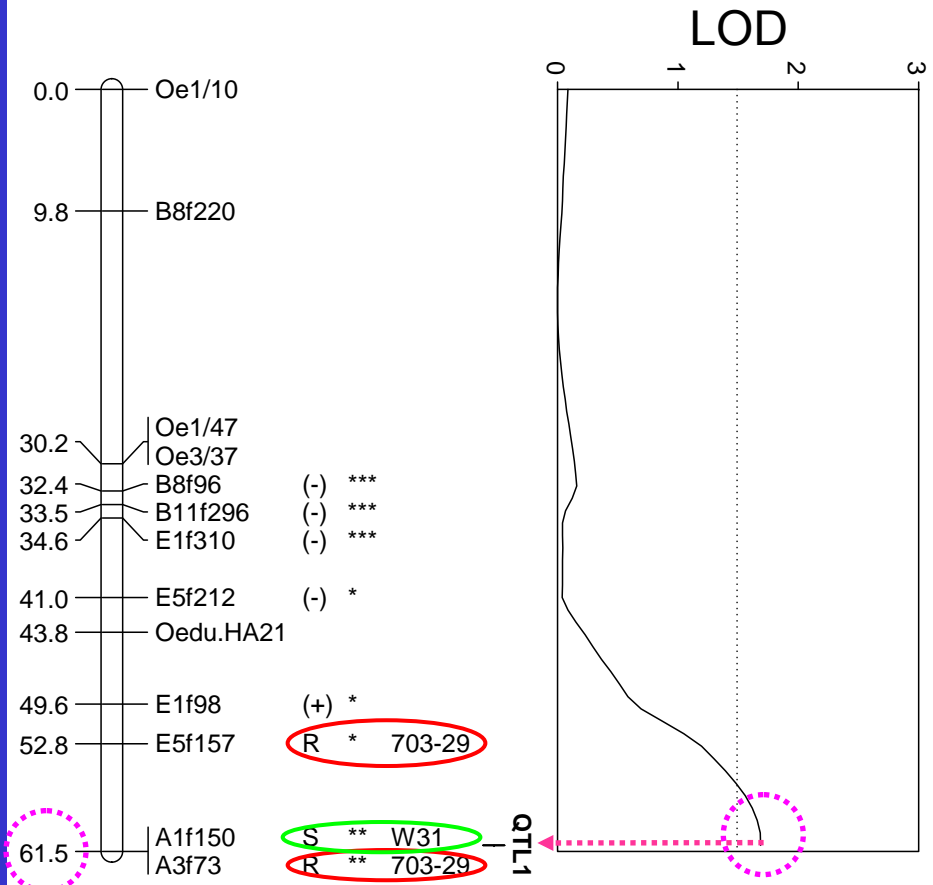

G10_410_8

R "resistant allele"

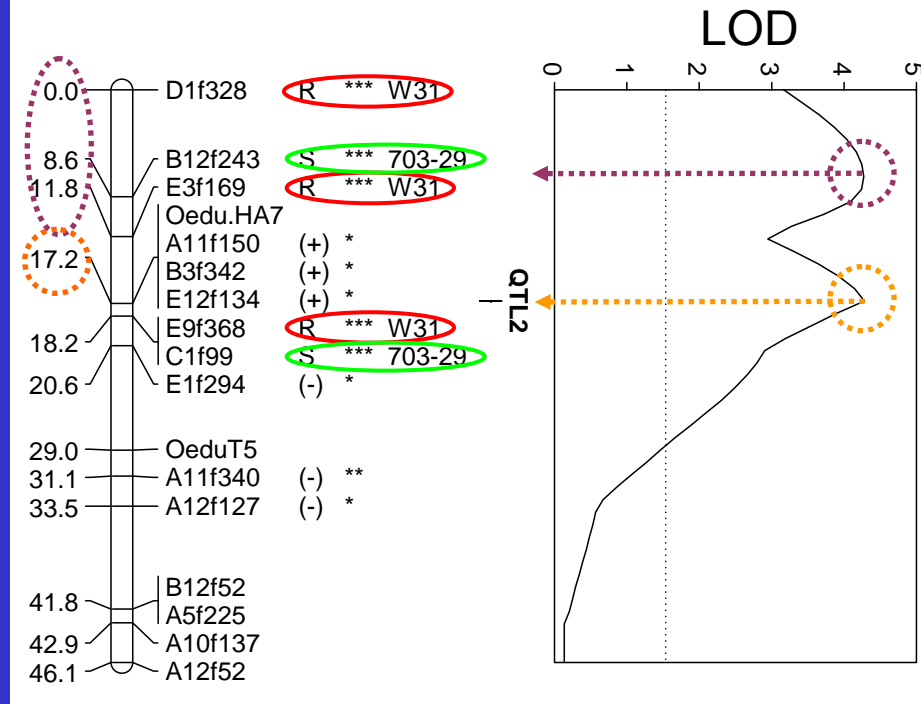

S "susceptible allele"

G3_410_8

61 cM, $p < 0.05$

G6_410_8

17 cM, $p < 0.01$

- Good concordance between multistage strategy, genetic mapping, QTL mapping
- Several markers of interest found (resistance, susceptibility)

Very promising results

Coming work

- Development of new microsatellites (ecogenics.ch)
- Increase the density of markers on the linkage map, allowing a more precise localization of QTLs
- SSH library underway (identification of candidate genes for bonamiosis resistance)
