Age estimation of the megrim (Lepidorhombus wiffiagonis) from the Celtic Sea and the Bay of Biscay

Megrim is a benthic species found throughout the North-east Atlantic and Western Mediterranean Sea. Sexual maturity occurs around 4 years old, which corresponds to a size of 25 cm for males and 28 for females. Longevity is estimated at 13 years.

Growth zones correspond to mineral opaque zones, deposited in summer when food availability is important. During winters, growth slows down, what is shown by translucent zones, made principally of organic matrix.

The otolith is immersed in water and read in its entirety under microscope using reflected light, which allows the observation of the nucleus and growth areas.

Age estimations of megrim caught during the first quarter of the year.
