Use of passive and active tracers in the biogeochemical-3D hydrodynamical ECO-MARS3D model to assess the role of river inputs on coastal zone of France, British Channel and southern North Sea

M. Dussauze, A. Ménesguen, F. Dumas
Département d’Ecologie Côtière IFREMER/Centre de Brest/France

Passive tracking method (hydrodynamical model alone)

- Conservative tracer (concentration 1) set only in the tracked river.
- The model ECO-MARS3D provides for each mesh of the domain daily values of tracer from 2000 to 2007.
- The distribution function of the 2920 values is calculated for each mesh of the surface layer.
- Percentile 10, 50 and 90 are deduced.

Active tracking method (biogeochemical model): Tracking any evolutive signature in a distributed trophic network

For the biogeochemical state variable $B_i$, having the signature $S(B_i)$:

- the current mass evolution equation is:
  \[ \frac{dB_i}{dt} = \text{sources}(B_1, B_2, ..., B_n, t) - \text{sinks}(B_1, B_2, ..., B_n, t) \]

- the new « signed mass » evolution equation is:
  \[ \frac{dB_s}{dt} = \text{sources}(B_1, B_2, ..., B_n, t) \times S(\text{source}) - \text{sinks}(B_1, B_2, ..., B_n, t) \times A(B_s) \]

- the signature $S(B_i)$ is:
  \[ S(B_i) = \frac{B_s}{B_i} \]

- the age $A(B_s)$ is:
  \[ A(B_s) = \frac{B_{sa}}{B_s} \]

Examples of nitrogen tracking (for the Loire river)

The pattern of the percentage of nitrogen from Loire in each compartment is very similar to the statistical marine receiving area described above. The percentage of nitrogen coming from Loire river is:
- between 20 and 30% (aged of less than 1 year) in the area closed to the estuary
- around 5-10% (aged of about 1.5 year) in the Western Channel
- about 2% (aged of about 3 years) in the entrance of the North Sea.

When going into more and more higher trophic levels (nitrate=>diatoms=>mesozooplankton=>benthic detritus), the percentage of nitrogen coming from the Loire river increases in the entrance of the Channel.
