## Contents

Executive Summary .....  .1
1 Introduction .....  2
1.1 Participants .....  2
1.2 Terms of Reference .....  2
1.3 Summary by Stock .....  4
1.4 Data available ..... 12
1.5 Stock Data Problems Relevant to Data Collection ..... 15
1.6 Consideration of protected species bycatch in the context of stock assessment work ..... 15
1.7 Revision of the MSY reference points ..... 15
1.8 Revision of the estimated landings from Spain from 2011 to 2014 ..... 16
1.9 Unallocated landings ..... 16
1.10 Use of InterCatch by WGBIE. ..... 16
1.11 Stock annexes ..... 16
1.12 Proposals for future benchmarks ..... 17
1.12.1 Benchmark planning ..... 18
1.12.2 Longer-term benchmark planning ..... 18
1.13 Mixed Fisheries considerations ..... 18
1.14 Assessment and forecast auditing process ..... 19
1.15 Ecosystem overviews ..... 20
1.16 References ..... 21
2 Description of Commercial Fisheries and Research Surveys ..... 28
2.1 Fisheries description ..... 28
2.1.1 Celtic - Biscay Shelf (Subarea VII and Divisions VIIIa,b,d) ..... 28
2.1.2 Atlantic Iberian Peninsula Shelf (Divisions VIIIc and IXa) ..... 31
2.2 Description of surveys ..... 33
2.2.1 Spanish groundfish survey (SpGFS-WIBTS-Q4) ..... 33
2.2.2 Spanish Porcupine groundfish survey (SpPGFS-WIBTS-Q4) ..... 34
2.2.3 Cadiz groundfish surveys - Spring (SPGFS-cspr-WIBTS-Q1) and Autumn (SPGFS-caut-WIBTS-Q4) ..... 34
2.2.4 Portuguese groundfish survey October (PtGFS-WIBTS-Q4) ..... 34
2.2.5 Portuguese crustacean trawl survey / Nephrops TV survey offshore Portugal (PT-CTS (UWTV (FU 28-29)). ..... 34
2.2.6 Portuguese winter groundfish survey/Western IBTS 1st quarter (PtGFS-WIBTS-Q1) ..... 35
2.2.7 French EVHOE groundfish survey (EVHOE-WIBTS-Q4) ..... 35
2.2.8 French RESSGASC groundfish survey (RESSGASC) ..... 35
2.2.9 French Bay of Biscay sole beam trawl survey (ORHAGO) ..... 35
2.2.10 French Nephrops survey in the Bay of Biscay (LANGOLF) ..... 35
2.2.11 UK west coast groundfish survey (UK-WCGFS) ..... 35
2.2.12 English fisheries science partnership survey (FSP-Eng- Monk) ..... 36
2.2.13 English Western English Channel Beam Trawl Survey. ..... 36
2.2.14 English Bottom Trawl Survey ..... 36
2.2.15 Irish groundfish survey (IGFS-WIBTS-Q4) ..... 36
3 Anglerfish (Lophius piscatorius and Lophius budegassa) in Divisions VIIb-k and VIIIa,b,d ..... 37
3.1 General ..... 37
3.1.1 Summary of ICES advice for 2015 and management for 2014 and 2015 ..... 37
3.1.2 Landings ..... 37
3.1.3 Discards ..... 38
3.2 Anglerfish (L. piscatorius) in Divisions VIIb-k and VIIIa,b,d ..... 40
3.2.1 Data ..... 40
3.2.1.1 Commercial Catch ..... 40
3.2.1.2 Commercial LPUE ..... 40
3.2.1.3 Surveys data ..... 40
3.2.1.3.1 The French EVHOE-WIBTS-Q4 survey ..... 40
3.2.1.3.2 The Spanish Porcupine Groundfish Survey (SPPGFS (WIBTS-Q4)) 41
3.2.1.3.3 The Irish Groundfish Survey (IGFS-WIBTS-Q4) ..... 41
3.2.2 Conclusion ..... 41
3.2.3 Comments on the assessment ..... 42
3.3 Anglerfish (L. budegassa) in Divisions VIIb-k and VIIIa,b,d ..... 52
3.3.1 Data ..... 52
3.3.1.1 Commercial Catch ..... 52
3.3.1.2 Commercial Effort and LPUE ..... 52
3.3.1.3 Surveys data ..... 52
3.3.1.3.1 The French EVHOE-WIBTS-Q4 survey ..... 52
3.3.1.3.2 The English Fisheries Science Partnership survey. ..... 53
3.3.1.3.3 Other surveys ..... 53
3.3.2 Conclusion ..... 53
3.3.3 Comments on the assessment ..... 54
4 Anglerfish (Lophius piscatorius and L. budegassa) in Divisions VIIIc and IXa ..... 63
4.1 General ..... 63
4.2 Summary of ICES advice for 2015 and management for 2014 and 2015 ..... 64
4.3 Anglerfish (L. piscatorius) in Divisions VIIIc and IXa ..... 65
4.3.1 General ..... 65
4.3.1.1 Ecosystem aspects ..... 65
4.3.1.2 Fishery description ..... 65
4.3.2 Data ..... 65
4.3.2.1 Commercial catches and discards ..... 65
4.3.2.2 Biological sampling ..... 66
4.3.2.3 Abundance indices from surveys ..... 67
4.3.3 Assessment ..... 68
4.3.3.1 Input data ..... 68
4.3.3.2 Model ..... 68
4.3.3.3 Assessment results ..... 68
4.3.3.4 Historic trends in biomass, fishing mortality and recruitment ..... 69
4.3.3.5 Retrospective pattern for SSB, fishing mortality, yield and recruitment ..... 69
4.3.4 Catch options and prognosis ..... 69
4.3.4.1 Short-term projections ..... 69
4.3.4.2 Yield and biomass per recruit analysis ..... 69
4.3.5 Biological Reference Points of stock biomass and yield. ..... 70
4.3.6 Comments on the assessment ..... 70
4.3.6.1 Quality considerations ..... 70
4.3.7 Management considerations ..... 70
4.3.8 References ..... 70
4.4 Anglerfish (Lophius budegassa) in Divisions VIIIc and IXa ..... 91
4.4.1 General ..... 91
4.4.1.1 Ecosystem aspects ..... 91
4.4.2 Fishery description ..... 91
4.4.3 Data ..... 91
4.4.3.1 Commercial catches and discards ..... 91
4.4.3.2 Biological sampling ..... 92
4.4.3.3 Abundance indices from surveys ..... 92
4.4.3.4 Commercial catch-effort data ..... 92
4.4.4 Assessment ..... 93
4.4.4.1 Input data ..... 93
4.4.4.2 Model ..... 93
4.4.4.3 Assessment results ..... 94
4.4.4.4 Sensitive analyses ..... 94
4.4.5 Projections ..... 95
4.4.6 Biological Reference Points ..... 95
4.4.7 Comments on the assessment ..... 95
4.4.8 Quality considerations ..... 96
4.4.9 Management considerations ..... 96
5 Megrim (Lepidorhombus whiffiagonis) in Divisions VIIb-k and VIIIa,b,d ..... 110
5.1 General ..... 110
5.1.1 Fishery description ..... 110
5.1.2 Summary of ICES Advice for 2015 and Management applicable for 2014 and 2015 ..... 110
5.2 Data. ..... 110
5.2.1 Commercial catches and discards ..... 110
5.2.2 Biological sampling ..... 111
5.2.3 Surveys data ..... 111
5.2.4 Commercial catch and effort data. ..... 112
5.3 Assessment ..... 113
5.3.1 Data Exploratory Analysis ..... 114
5.3.2 Model ..... 115
5.3.3 Results ..... 115
5.4 Retrospective pattern ..... 116
5.5 Short term forecasts ..... 116
5.6 Conclusions ..... 116
5.7 Recommendations on the procedure for assessment updates and further work ..... 117
6 Megrims (Lepidorhombus whiffiagonis and L. boscii) in Divisions VIIIc and IXa ..... 146
6.1 Megrim (L. whiffiagonis) in Divisions VIIIc and IXa ..... 147
6.1.1 General ..... 147
6.1.2 Data ..... 147
6.1.2.1 Commercial catches and discards ..... 147
6.1.2.2 Biological sampling ..... 147
6.1.2.3 Abundance indices from surveys ..... 148
6.1.2 $\quad$ Commercial catch-effort data ..... 149
6.1.3 Assessment ..... 150
6.1.3.1 Input data ..... 150
6.1.3.2 Model ..... 150
6.1.3.3 Assessment results ..... 150
6.1.3.4 Year class strength and recruitment estimations ..... 151
6.1.3.5 Historic trends in biomass, fishing mortality and recruitment ..... 152
6.1.3.6 Catch Options and prognosis ..... 152
6.1.3.7 Short-term projections ..... 152
6.1.3.8 Yield and biomass per recruit analysis ..... 152
6.1.4 Biological reference points ..... 153
6.1.5 Comments on the assessment ..... 153
6.1.6 Management considerations ..... 153
6.2 Four-spot megrim (Lepidorhombus boscii) ..... 191
6.2.1 General ..... 191
6.2.2 Data ..... 191
6.2.2.1 Commercial catches and discards ..... 191
6.2.2.2 Biological sampling ..... 191
6.2.2.3 Abundance indices from surveys ..... 191
6.2.2.4 Commercial catch-effort data ..... 192
6.2.3 Assessment ..... 193
6.2.4 Model. ..... 193
6.2.4.1 Assessment results ..... 194
6.2.4.2 Year class strength and recruitment estimations ..... 194
6.2.4.3 Historic trends in biomass, fishing mortality, and recruitment ..... 194
6.2.5 Catch options and prognosis ..... 195
6.2.5.1 Short-term projections ..... 195
6.2.5.2 Yield and biomass per recruit analysis ..... 195
6.2.5.3 Biological reference points ..... 195
6.2.6 Comments on the assessment ..... 196
6.2.7 Management considerations ..... 196
6.3 Combined Forecast for Megrims (L. whiffiagonis and L. boscii) ..... 196
7 Bay of Biscay Sole ..... 237
7.1 General ..... 237
7.1.1 Ecosystem aspects ..... 237

## Executive Summary

The ICES Working Group for the Bay of Biscay and the Iberic waters Ecoregion (WGBIE) met in Copenhagen, Denmark during 4-10 May 2015. There were 22 stocks in its remit distributed from ICES Divisions IIIa to IXa though mostly distributed in Sub Areas VII, VIII and IX. There were 21 participants. The group was tasked with carrying out stock assessments and catch forecasts and providing a first draft of the ICES advice for 2015 for 7 stocks. For the remaining stocks, the group had to update catch information and indices of abundance when needed. Depending on the result of this update, namely if it would change the perception of the stock, the working group had (or not) to draft a new advice.

Analytical assessments using age-structured models were conducted for the northern and southern stocks of megrim and the Bay of Biscay sole, whereas the two hake stocks and one southern stock of anglerfish were assessed using models that allow the use of only length-structured data (no age data). A surplus-production model, without age or length structure, was used to assess the second southern stocks of anglerfish. No analytical assessments have been provided for the northern stocks of anglerfish after 2006. This is mostly due to ageing problems and to an increase in discards in recent years, for which there is no reliable data at the stock level. The state of stocks for which no analytical assessment could be performed was inferred from examination of commercial LPUE or CPUE data and from survey information.

Three nephrops stocks from the Bay of Biscay and the Iberian waters are scheduled for benchmark assessments at the end of 2016. The WGBIE meeting spent some time planning this benchmark (see Annex 06) together with longer term benchmarks (2017 and after, see section 1.) for sea bass in the Bay of Biscay and all anglerfish stocks assessed by the WG. For the northern megrim stock, the group recommend to schedule an interbenchmark meeting before the end of 2015, in order to incorporate missing discard data and develop a prediction framework based on the current assessment model.

A recurrent issue significantly constrained the group's ability to address the terms of reference this year. Despite an ICES datacall with a deadline of 3 weeks before the meeting, data for several stocks were only available at the start of the meeting which lead to increase in workload during the working group, as in that case, the assessments could not be carried out in National Laboratories prior to the meeting as mentioned in the ToRs. This is an important matter of concerns for the group members.

Section 1 of the report presents a summary by stock and discusses general issues. Section 2 provides descriptions of the relevant fishing fleets and surveys used in the assessment of the stocks. Sections 3 to 18 contain the single stock assessments.

## 1 Introduction

### 1.1 Participants

| NAME | Country |
| :--- | :--- |
| Esther Abad | Spain |
| Ricardo Alpoim | Portugal |
| Michel Bertignac | France (Chair) |
| Maria de Fatima Borges | Portugal |
| Santiago Cerviño | Spain |
| Anne Cooper | ICES Secretariat |
| Mickael Drogou | France |
| Spyros Fifas | France |
| Hans Gerritsen | Ireland |
| Joao Figueiredo Pereira | Portugal |
| Dorleta Garcia | Spain |
| Ane Iriondo | Spain |
| Muriel Lissardy | France |
| Simon Northridge | United Kingdom |
| Iñaki Quincoces | Spain |
| Lisa Readdy | United Kingdom |
| Camilo Saavedra | Spain |
| Paz Sampedro | Spain |
| Cristina Silva | Portugal |
| Audric Vigier | France |
| Yolanda Vila | Spain |

Contact details for each participant are given in Annex 1.

### 1.2 Terms of Reference

2014/2/ACOM12. The Working Working Group for the Bay of Biscay and Iberian waters Ecoregion (WGBIE), chaired by Michel Bertignac (France), will meet in the ICES Secretariat, 4-10 May 2015 to:
a) Address generic ToRs for Regional and Species Working Groups (see table below)
b) Assess the progress on the benchmark preparation of Nephrops;

The assessments will be carried out on the basis of the stock annex in National Laboratories, prior to the meeting. The data to perform the assessment should be available on the 10 April 2015 according to the Data call 2015, which was send out on 3 February 2015. This will be coordinated as indicated in the table below.

WGBIE will report by 1 June 2015 for the attention of ACOM. The group will report on the ACOM guidelines on reopening procedure of the advice before 14 October and will report on reopened advice before 29 October.

### 1.3 Summary by Stock

The stocks assessed within WGBIE are distributed from ICES Division IIIa to IXa (Figure 1.1). Figure 1.2 shows the distribution areas of the Nephrops Functional Units (FUs).

## Anglerfish (Lophius piscatorius and L. budegassa) in Divisions VIIb-k and VIIIa,b,d

Both species are caught on the same grounds and by the same fleets and are usually not separated by species in the landings. Anglerfish is an important component of mixed fisheries taking hake, megrim, sole, cod, plaice and Nephrops. Spain and France together contribute about $80 \%$ of total stock landings. The TAC for both species combined was set at 42496 t for 2014 and 2015. For 2014, landings were estimated at 36200 t close to the record level estimated for 2013.

Age determination problems and an increase in discards in recent years have prevented the performance of an analytical assessment since 2007. Since then, the assessment is based on examining commercial LPUEs and survey data (biomass, abundance indices and length distributions from surveys). Four surveys are available, covering the whole distribution area of the stocks and with little overlap between them.

For L. piscatorius the available data indicate that the biomass has been increasing as a consequence of the good recruitment observed in 2001, 2002 and 2004 and has stabilised in recent years. There is evidence of good recruitments in 2008, 2009, 2010 and 2011. 2008 and 2009 recruitments have entered the fishery giving one of the higher yields of the time series. Recruitment in 2012 and 2013 were lower than in previous years but there is indication that the 2014 recruitment could be high.

For L. budegassa survey data give indication that the biomass has increased since the mid 2000's as a consequence of several good incoming recruitments. A strong recruitment was observed in 2008. The EVHOE-WIBTS-Q4 shows evidence of large recruitment in 2011, 2012 and 2013 and slightly lower level for 2014. Length frequency distributions from the two available surveys show contradictory signals for 2009, 2011 and 2012 recruitments, but the working group considers that the trend of EVHOE is more representative due to the larger coverage of the survey.

In view of available data, the WG considers that fishing at present level should not harm both stocks. More details on the anglerfish assessment can be found in Section 3.

## Anglerfish (L. piscatorius and L. budegassa) in Divisions VIIIc and IXa

Both species are caught in mixed bottom trawl fisheries and in artisanal fisheries using mainly fixed nets. The two species are usually landed together for the majority of commercial categories and they are recorded together in the ports' statistics. Landings of both species combined in 2014 were 2989 t . The combined TAC was set at 2629 t in 2014 and 2987t in 2015.

The two species are assessed separately, using a surplus-production model (software ASPIC), tuned with commercial LPUE series for L. budegassa and a length based SS3 implementation for L. piscatorius.
Biomass of L. piscatorius decreased during the 1980s and early 1990s, but has progressively increased over the last two decades to 7814 tonnes in 2014. No biomass reference points have been determined for this stock. Fishing mortality peaked during the late

1980's but has since declined close to $\mathrm{Fmsy}^{\text {( }} \mathbf{( 0 . 1 9 )}$ from 2011 to 2013. F increased in 2014 to 0.25 . Recruitment has been relatively low in recent years and shows little evidence of strong year classes since 2001.

Trends in relative biomass of $L$. budegassa indicate a steady decrease since the beginning of the series until 2001. Since then a slight recovery was observed and in 2015 the biomass is estimated to be at $98 \%$ of Bmš. Fishing mortality remained at high levels between late eighties and late nineties, dropping after that. In 2014, fishing mortality is estimated to be below Fmsy.

Although the stocks are assessed separately, they are managed together.
More details are provided in Section 4.

## Megrim (Lepidorhombus whiffiagonis) in Divisions VIIb-k and VIIIa,b,d

L. whiffiagonis in Div. VIIb-k and VIIIa,b,d is caught in a mixed demersal fishery catching anglerfish, hake and Nephrops, both as a targeted species and as valuable bycatch. The 2014 and 2015 TAC were set at 19101 t , including a $5 \%$ contribution of L. boscii in the landings for which stock there is no assessment. Landings in recent years were relatively stable around 15000 t . Discarding of smaller megrim is substantial and also includes individuals above the minimum landing size of 20 cm . The discards were variable, between 2000 and 4000 t

After several years without assessment, a Bayesian catch at age model was investigated during a benchmark held in 2012. Due to underlying issues with the catch at age data, it was concluded that the model could only be considered to be indicative of trends in the fishery. For this year assessment, the use of the Bayesian statistical catch-at-age model gives very promising results and the model is able to address the heterogeneity in the Northern Megrim data in a very satisfactory way. The model fit to the data is adequate and the WG considers that the current assessment can be fully accepted and not only as indicator of trend. However, some work is still needed in order to develop the basis for short term projection and that is the reason why, in this year assessment, no projections have been carried out directly from the assessment. The development of framework for projections based on the bayesian stock assessment model will be conducted during an Inter Benchmark planned at the end of 2015 and made available to the WG next year. Catch, landing and discard data and survey indices do not appear to indicate the presence of important change in trends of recruitment or the overall biomass.
Details of the available data and analysis carried out during the WG are provided in Section 5.

## Megrims (L. whiffiagonis and L. boscii) in Divisions VIIIc and IXa

Southern megrims L. whiffiagonis and L. boscii are caught in mixed fisheries targeting demersal fish including hake, anglerfish and Nephrops and are not separated by species in the landings. The majority of the catches are taken by Spanish trawlers. Landings of both species combined in 2014 were 1531 t (of which $80 \%$ correspond to L. whiffiagonis). The agreed combined TAC for megrim and four-spot megrim in ICES Divisions VIIIc and IXa was 2257 t in 2014 and 1377 t in 2015.
The species are assessed separately, using XSA.
For L. whiffiagonis the assessment indicates that fishing mortality has increased since 2011. The SSB values in 2007-2010 were the lowest in the series but since 2011, SSB has
increased to a value close to the average of the historical series. After a very high recruitment (at age 1) in 2010 the recruitment has decreased to an average value.

For L. boscii the assessment indicates that SSB decreased gradually from 1989 to 2001, the lowest value in the series, and has since increased. In 2014 the SSB is estimated to be one of the highest of the series. Recruitment has fluctuated around 45 million fish during all the series. Very weak year classes are found in 1993 and 1998. The highest value occurred in 2014 at 121 millions but needs to be confirmed when more data will be available. Estimates of fishing mortality values show two different periods: an initial period with values around 0.5 from 1989 to 1996 followed by a decreasing trend with the lowest value estimated in 2012 ( $\mathrm{F}=0.22$ ). In 2013 and 2014, F has increased ( $\mathrm{F}=0.39$ in 2014).

Details of the assessments are presented in Section 6.

## Sole in Divisions VIIIa,b (Bay of Biscay)

Bay of Biscay sole is caught in ICES Divisions VIIIa and b. The fishery has two main components: one is a French gillnet fishery directed at sole (about two thirds of total catch) and the other one is a trawl fishery (French otter or twin trawlers and Belgian beam trawlers). The 2014 TAC was set at 3800 t and the 2015 TAC is the same at 3800 t. Landings in 2014 were 3924 t.

Discards are not included in the assessment. Discards are considered to be low for the ages included in the assessment, which starts at age 2.

In 2013, a benchmark workshop recommended the inclusion of the ORHAGO survey in order to provide such information and this inclusion was accepted. This year, an attempt was made to update the reference points following the framework of WKMSYREF2 and WKMSYREF2. However, the group did not have enough confidence in the results to propose new reference points. The group considers that the current Fmsy proxy is not appropriate and suggests that further work is needed.

Since 1984, fishing mortality has gradually increased, peaking in 2002 and decreased substantially the following two years. After 2005, F was stable around 0.42 (= Fpa). In 2014 F is estimated at 0.49 , above Fpa and Fmsy. The SSB trend in earlier years increases from 1984 to a high value in 1993. Afterwards SSB shows a continuous decrease until 2003, the lowest value of the series. SSB has been increasing and was above Bpa from 2010 to 2013. In 2014, SSB has dropped again below Bpa at 10600 t . The recruitment values are lower since 1993. Between 2004 and 2008 the series is stable around 17 or 18 million and the 2007 year class is the highest value since 1984. The 2010 and 2011 values are closed to the GM93-12 ( 21.8 million). However, the 2012 and 2013 values are the lowest of the series ( 11.1 million and 10.7 million respectively). In 2014, the recruitment increased to 25 million.

As in last year, the group considers that, with the inclusion of the ORHAGO survey, the estimate of the recruitment for last year (2014 in this year assessment) has improved compared to previous assessment and decided to keep the value estimated by the assessment model.

Details on the assessment are in Section 7.

## Sole in subdivisions VIIIc and IXa

Portugal and Spain are the main participants in this fisheries. Solea solea is mainly caught with gillnets and trammel nets. In Portugal Solea solea is caught together with
and other similar species Solea senegalensis and Pegusa lascaris and it is only in recent years that official catches are reported separated by species. In 2014, total landings of solea solea were 681 t . The available information is insufficient to evaluate stock trends and exploitation status. Therefore, the state of the sole in Divisions VIIIc and IXa is unknown. New data (landings) available for this stock do not change the perception of its status.

Details on the assessment are in Section 8

## Hake in Division IIIa, Subareas IV, VI and VII and Divisions VIIIa,b,d (Northern stock)

Hake is caught in nearly all fisheries in Subareas VII and VIII and also in some fisheries in Subareas IV and VI. In recent years, Spain accounted for the main part of the landings, followed by France. Stock landings have been steadily increasing throughout the last decade, from 36700 t in 2001 to 89800 t in 2014, the highest value since 1963. In 2014, landings were above the 2014 TAC (81 800 t).

The stock had a benchmark assessment in February 2014 (WKSOUTH, 2014). One of the main objectives of the workshop was to address a strong retrospective pattern which appeared in 2013 assessment. It was felt that this pattern was mainly due to changes in the size of hake caught by the majority of the fleets which the assessment model had difficulties to cope with. Most of the benchmark workshop was thus focused on obtaining the most appropriate way to account for the changes in retention and selectivity for the two most influential fleets and the group agreed that the model was an improvement in terms of taking into account the changes in stock structure and accepted the assessment model with the proviso that the model be developed and fine tuned as more data and information become available

This year, the assessment was carried out following the stock annex revised during the benchmark and although the retrospective patterns are still present, they are less important than last year and limited to the recent years. The recruitment appears to fluctuate without substantial trend over the whole series. The recruitment estimated for 2008 is the highest in the whole series ( 700 million). In 2014, the recruitment decreased below mean level ( 240 million). From high levels at the start of the series (100 000 t in 1980), the SSB has decreased steadily to a low level at the end of the 90 s ( 25000 t in 1998). Since that year, SSB has increased to the highest value of the series in 2012 (218 000 t ) and decreased slightly in 2013 and 2014. The fishing mortality is calculated as the average annual $F$ for sizes $15-80 \mathrm{~cm}$. This measure of $F$ is nearly identical to the average $F$ for ages $1-5$. Values of $F$ increased from values around $0.5-0.6$ in the late 70 s and early 80 s to values around 1.0 during the 90 s. They declined sharply afterwards to 0.34 in 2012 and increased up to 0.34 in 2014.

Details about the assessment of this stock are provided in Section 9.

## Hake in Divisions VIIIc and IXa

Hake in Divisions VIIIc and IXa is caught in a mixed fishery by Spanish and Portuguese trawlers and artisanal fleets. Spain accounts for the main part of the landings. Total landings in 2013 were 11661 t and 12011 t in 2014. Total discards in 2013 were 2553 t and 2602 t in 2014.

The southern hake stock had a benchmark assessment in February 2014 (WKSOUTH). One of the main issues addressed during the benchmark workshop was related to the difficulties encountered by the GADGET model in its search for the set of parameters
that maximise the likelihood function. The work confirmed that the model fitting procedure is finding a genuine optimum and can thus continue to be used as the assessment model. Further work to improve the optimisation characteristics of the model has been suggested.

The recruitment (age 0) is highly variable and presents two different periods: one from 1982 to 2003 with mean figures around 70 million, ranging from 40 to 120, and a recent period from 2004 to latest with a mean of 121 million ranging from 70 to 180 million. Fishing mortality increased from the beginning of the time series ( $\mathrm{F}=0.36$ in 1982) peaking in 1995 at 1.18; declining to 0.78 in 1999 and remaining relatively stable until 2009 ( $\mathrm{F}=1.01$ ). F then progressively decreased to reach 0.68 in 2014. The SSB was very high at the beginning of the time series with values around 40000 t , then decreased to a minimum of 5 800t in 1998. Since then biomass has continuously increased, reaching 18840 t in 2014, slightly above the 2012 figure ( 17400 t )

Details on the assessment of this stock are in Section 10.

## Nephrops in ICES Division VIIIa,b

There are two Functional Units in ICES Division VIIIa,b: FU 23 (Bay of Biscay North) and FU 24 (Bay of Biscay South), see Figure 1.2. Nephrops in these FUs are exploited by French trawlers almost exclusively. Landings declined until 2000, from 5900 t in 1988 to 3100 t in 2000. After that year, they increased again to around 3700 t , staying at that level for some time. Since 2006 landings have been around 3,300 t. In 2012 and 2013, a reduction in the landings occurred ( 2520 t in 2012, 2380 t in 2013) followed by an increase at 2800 t in 2014. The agreed TAC for 2015 was 3899 t .

A French regulation increased the minimum landing size in 2006 and several effort and gear selectivity regulations have also been put in place in recent years. The use of selective devices for trawlers targeting Nephrops became compulsory in 2008. All these measures are expected to be contributing in various ways to the changing patterns of landings and discards observed recently. In general, discards values after year 2000 have been higher than in earlier years, although sampling only occurred on a regular basis starting from 2003, so information about discards is considerably weaker for the earlier period.
This stock underwent an inter-benchmark protocol in 2012. The outcome of this process was inconclusive with a recommendation that the work undertaken should be considered in a full benchmark setting.
No quantitative analytical assessment was carried out this year, however, based on the stability of the commercial LPUEs in recent years, the WG considered that the perception of the stock was not changed compared to last year assessment.

Details can be found in Section 11.

## Nephrops in ICES Division VIIIc

There are two Functional Units in Division VIIIc (Figure 1.2): FU 25 (North Galicia) and FU 31 (Cantabrian Sea).

Nephrops are caught in the mixed bottom trawl fishery in the North and Northwest Iberian Atlantic. Landings from both FUs have declined dramatically in recent years reaching less than 10t in each FU in 2014, below the TAC in recent years, which has not been restrictive. The TACs were set at 67 t and 60 t for the whole Division VIIIc for 2014 and 2015, respectively.

A recovery plan for southern hake and Iberian Nephrops stocks has been in force since 2006. The aim of the recovery plan is to rebuild the stocks within 10 years, with a reduction of $10 \%$ in F relatively to the previous year and the TAC set accordingly (Council Regulation (EC) No. 2166/2005).
According to the ICES data-limited approach, both stocks are considered as category 3.1.4. The two stocks are assessed by the analysis of the LPUE series trend. The perception of the stocks is the same as last year indicating an extremely low abundance level.
Additional details are provided in Section 12.

## Nephrops in ICES Division IXa

There are five Functional Units in Div. IXa (Figure 1.2): FU 26 (West Galicia); FU 27 (North Portugal); FU 28 (Alentejo, Southwest Portugal); FU 29 (Algarve, South Portugal) and FU 30 (Gulf of Cádiz).
Landings in 2014 from the five FUs combined were 212 t . The TAC set for the whole Division IXa was 221 t and 211 t for 2014 and 2015.

A recovery plan for southern hake and Iberian Nephrops stocks has been in force since 2006. The aim of the recovery plan is to rebuild the stocks within 10 years, with a reduction of $10 \%$ in F relatively to the previous year and the TAC set accordingly (Council Regulation (EC) No. 2166/2005).
FU 26+27 (West Galicia and North Portugal): The fishery shares the same characteristics of that in Division VIIIc, described above.

Landings are reported by Spain and minor quantities by Portugal. Spanish fleets fish in FU 26 and FU 27, whereas Portuguese artisanal fleets fish with traps in FU 27. Two periods can be distinguished in the time series of landings available 1975-2014. During 1975-1989, the mean landing was 680 t , fluctuating between 575 and 800 t ap-proximately. Since 1990 onwards there has been a marked downward trend in landings, being below 50 t from 2005 to 2011. In the three last years, landings continued to decrease and were below 10 t . Discards rates are negligible.

According to the ICES data-limited approach, this stock is considered as category 3.1.4. These FU 26-27 are assessed by the analysis of the LPUE series trend, as was done in 2012. The perception of the stocks is the same as last year indicating an extremely low abundance level.

FU 28+29 (SW and S Portugal): Nephrops is taken by a multi-species and mixed bottom trawl fishery. The trawl fleet comprises two components, one targeting fish operating along the entire coast, and another one targeting crustaceans, operating mainly in the southwest and south, in deep waters. There are two main target species in the crustacean fishery, Norway lobster and deepwater rose shrimp, with different but overlapping depth distributions. In years of high rose shrimp abundance, the fleet directs its effort preferably to this species.

For the time period 1984 to 1992, the recorded landings from FUs 28 and 29 have fluctuated between 420 and 530 t , with a long-term average of about 480 t , falling drastically in the period 1990-1996, down to 132 t. From 1997 to 2005 landings have increased to levels observed during the early 1990s but decreased again in recent years. The value landings in 2009-2011 was approximately at the same level $(\approx 150 \mathrm{t}$ ), increasing to around 200 t in the years 2012-2014.

According the ICES data-limited approach, this stock is classified in the category 3.2.0. The advice is based on survey and fishery CPUE and effort trends. A standardized effort shows a consistent declining trend since 2005 reaching a historic low in 20092010. In the following years, the effort had a slight increase however still remaining at a low level. The fleet standardized CPUE, used as index of biomass, decreased in the period 2006-2011. The update of the index does not change the perception of the stock status, the index has been increasing in recent year.
FU 30 (Gulf of Cádiz): Nephrops in the Gulf of Cádiz is caught in a mixed fishery by the trawl fleet. Landings are markedly seasonal with high values from April to September. Landings were reported by Spain and minor quantities by Portugal. Landings increased from 100t in the mid 90s to a higher level at the beginning of the 2000s. Landings have decreased again until 2008 and then remained around 100t from 2008 to 2012. They have dropped to 26 t in 2013 and 15 t in 2014. The reason for this drop is that the quota in 2012 was exceeded and the European Commission applied a sanction which will be paid in 3 years. So, the Nephrops fishery was closed almost whole 2013 and vessels could only went fishing Nephrops a few days in summer and winter.

According to the ICES data-limited approach, this stock is considered as category 3.2.0. FU 30 is assessed by the analysis of the LPUE series trend. The update of the LPUE series and abundance survey index shows two conflicting signals. The LPUE decreasing while the survey index is increasing however, WG express concerns over the ability of those two indexes to reflect variations in the abundance in 2013 and 2014. The WG considers that no new information is available to change the perception of the status of the stock.

The five Nephrops FUs (assessed as 3 separate stocks) are managed jointly, with a single TAC set for the whole of Division IXa. This may lead to unbalanced exploitation of the individual stocks. The northernmost stocks (FUs 26-27) are at extremely low levels, whereas the southern ones (FUs 28-29 and FU 30) are in better condition. To protect the stock in these Functional Units, management should be implemented at the Functional Unit level.

Additional details can be found in Section 13.

## European Seabass in Division VIIIa,b

Seabass in the Bay of Biscay are targeted by France (more than $90 \%$ of international landings) by line fisheries which take place mainly from July to October, by nets, pelagic trawlers, and in a mixed bottom trawl fisheries from November to April on pre spawning and spawning grounds when seabass aggregate. Since the late 90 s total landings are stable around 2500 t . Landing of netters have however increased since 2011 due to a decrease of sole quotas from 2011 and a redistribution of effort towards this species combined with good weather condition in 2014. Recreational fisheries are an important part of the total removals but these are not accurately quantified. Discards are known to take place but are not fully quantified. Anecdotal information suggests that discards may be very low in the area.

No stock assessment is carried out for this stock. According to the ICES data-limited approach, this stock was considered as category 5.2.0, so without information on abundance or exploitation. This year, an index of abundance based on standardised LPUEs has been proposed and the WG has suggested to consider the stock as category 3 .

Additional details can be found in Section 14.

## European Seabass in Division VIIIc, IXa

Spanish and Portuguese vessels represent almost of the total annual landings in the area IXa and VIIIc. Commercial landings represent 917 t in 2014. A peak of landings is observed in the early 90 's and in 2013, reaching more than $1000 t$, and lowest landings $(637 \mathrm{t})$ have been observed in 2004. No discards have been observed for this stock by the observer program.

No stock assessment is carried out. No information on abundance or exploitation is available and the stock is considered as category 5.2.0. This year, there are no new data available that change the perception of the stock.

Additional details can be found in Section 15.

## Plaice in Subarea VIII and Division IXa

Plaice (Pleuronectes platessa) are caught as a bycatch by various fleets and gear types covering small-scale artisanal and trawl fisheries. Portugal and France are the main participants in this fishery with Spain playing a minor role. Present fishery statistics are considered to be preliminary as there are concerns about the reliability of the French data from 2008-09. Landings may also contain misidentified flounder (Platichthys flesus) as they are often confounded at sales auctions in Portugal. The quantity of discarding is uncertain. For these reasons, the landings are unlikely to be a good indicator of total removals and ICES considers that it is not possible to quantify the catches.

This stock is currently ranked as a Data Limited Stock in category 5.2 as only landings data are available. This year, there are no new data available that change the perception of the stock.

Additional details can be found in Section 16.

## Pollack in Subarea VIII and Division IXa

Landings have been reported by the three countries with quota: France, Spain and Portugal. Pollack is exploited by several type of gears. The main part of the landings are made by gillnets and lines. Since the early 2000s, the landings have been relatively stable between 1500 t and 2000 t .

Discards estimates in the Spanish fleet indicate that the discards may be low.
The stock from is currently ranked as a Data Limited Stock in category 5.2 as there is information on landings only. This year, there are no new data available that change the perception of the stock.

Additional details can be found in Section 17.

## Whiting in Subarea VIII and Division IXa

Whiting (Merlangius merlangus) are caught in mixed demersal fisheries primarily by France and Spain. Present fishery statistics are considered to be preliminary. Total landings in recent years were stable around 2000 t . Landings may also contain misidentified Pollack (Pollachius pollachius). Whiting has never been recorded in Spanish discards and is negligible in Portuguese discards. However there are indications that some discarding occurs in the French fleet.

This species is at the southern extent of its range in the Bay of Biscay and Iberian Peninsula. It is not clear whether this is a separate stock from a biological point of view.

This stock from is currently ranked as a Data Limited Stock in category 5.2 as there is information on landings only. This year, there are no new data available that change the perception of the stock.

### 1.4 Data available

ICES launched a formal data call for WGBIE for the second time in 2015, in order to prepare the datasets for the working group and progress on the use of InterCatch. Catch (totals and/or age-length structured) and effort data according to species, country, area and métier were requested.

As shown in the table below not all countries managed to deliver data for all species by the deadline : only $30 \%$ of stock x country strata were uploaded ( 22 over 73 ). At the beginning of the meeting, $78 \%$ of stock $\times$ country strata ( 57 over 73 ) were uploaded either in IC or sent to ICES and stock coordinators as Accession (AC). For some stocks the data was sent directly to the stock coordinators. However, not all the data was available at the start of the meeting, which increased the workload for some stocks during the working group, as in that case, the assessments could not be carried out in National Laboratories prior to the meeting as mentioned in the ToRs. The missing data was however delivered during the WG and the group was able to update the assessment for all stocks that needed an update. Uploading the data into InterCatch was part of the data request but as a result, only few of the stocks among the 23 listed in the datacall used InterCatch as the only tool to compute the model entry files. For all other stocks, InterCatch was partly used (to download un-raised data) or not used at all, the data being also delivered directly to each stock coordinators in worksheet format.
For some stocks, the group noted that some data were very poor and recommends that a basic data check be carried out by the data providers before uploading the data in InterCacth. This includes checking if the total landings are consistent with the historical landing and checking the quality of the length or age frequency distributions.

The main data problems detected by the Working Group and for which action is required are described in the "Stock Data Problems" table included in Annex 07.

Several stocks assessed by the Group are managed by means of TACs that apply to areas different from those corresponding to individual stocks, notably in Subarea VII, as well as for the Nephrops FUs in VIIIc and IXa, or to a combination of species in the cases of anglerfish and megrim.

Biological sampling levels by country and stock are summarised in Table 1.3a and b.

### 1.5 Stock Data Problems Relevant to Data Collection

WGBIE identified the following issues for further discussion by the WGDATA in relation to stock data problems relevant to data collection. These are listed in the table included in Annex 07 of the report.

### 1.6 Consideration of protected species bycatch in the context of stock assessment work.

EU policy demands that fisheries management adopts an ecosystem approach, which includes taking account of the impacts of fishing on non-target species. Including protected species in stock assessment advice is also one of the aims of the EU funded project Myfish and this multispecies approach has been also one of the tasks of the ongoing Mareframe project. Simon Northridge gave an overview of the current state of the bycatch policy in the UE and highlighted that at least two species of cetacean - the common dolphin and the harbour porpoise - are regularly caught in a range of fishing gears targeting some of the principal target fish species in the region. There are no agreed measures to determine what an unacceptable level of cetacean bycatch might be, and there are only limited data on bycatch rates in many fisheries. However, certain gear types are considered by the scientific community dealing with marine mammal bycatch, to have relatively high bycatch rates, and some of these rates have been measured. Despite the lack of detailed assessment, there remain widespread public concerns about cetacean bycatch. There are at present no easy ways to integrate advice concerning cetacean bycatch with catch advice. Indeed ICES advice on cetacean bycatch has been widely ignored by managers, and ICES is seeking ways to ensure more integrated ways to present advice, incorporating environmental concerns into catch advice. The group considered how this might be done in the context of cetacean bycatch in the Biscay region and agreed that it would be useful to explore ways in which concerns about bycatch could be conveyed alongside catch advice. It was agreed that the hake stock assessment might provide a useful arena in which to explore some ideas. A multispecies model is being developed which incorporates common and bottlenose dolphins as main predators of hake. This model was presented during the meeting and their details are described into the working document (WD-9). However the model development is not still finished to provide advice in a mixed fisheries context. One possibility might involve looking at the partial effort levels that are currently being derived for different fleet segments and to try to link these with potential cetacean bycatch mortalities, which are known to be fleet segment dependent. Even in the absence of detailed data this might provide a way to explore the feasibility of considering impacts of fishing on non-target and target species simultaneously. However, bycatch rates provided by observers on board are almost the only way to obtain accurate bycatch estimates of the fleet. Therefore, observer programmes are urgently needed to obtain these estimates in Bay of Biscay (as required by the Council Regulation EC $812 / 2004$ for some fleets). In the absence of better information for now, it was agreed that S. Northridge would communicate with the members involved into the assessment of hake stocks who are undertaking work on deriving partial effort levels for hake fleet segments, to link these with likely or actual cetacean bycatch or mortality rates.

### 1.7 Revision of the MSY reference points

WGBIE attempted a revision of the MSY reference points for the Bay of Biscay sole stock using the guidelines developed under WKMSYREF2 and WKMSYREF3. The WG considered however that due mainly to the uncertainty associated with the stock-recruitment relationship, it was not in a position to propose any new values for the MSY
reference points and suggest that this was reconsidered during the ICES workshop on MSY ranges scheduled for next fall.

### 1.8 Revision of the estimated landings from Spain from 2011 to 2014

Until recent year, the Spanish landings were estimated by combining both biological information and fisheries statistics. These data were obtained, for the biological data, through the sampling of fishing trips and for fisheries statistics, from sales notes of the main landing ports. A gradual decline in sales notes quality was noticed over recent years leading to the development of a new method to estimate landings (see WD 03). This estimation is now based on the raising of the observed LPUE (Landings per Unit Effort) to the total effort, a method similar to the one used to estimate discards.

The method was first applied last year for the 2013 data (WGBIE, 2014) but some concerns were raised by the group as the landings of some species were found inconsistent with the historical series based on the former methodology. WGBIE thus requested that the 2011-2012 data be re-estimated using the new methodology, in order to facilitate comparison with the previous approach.

This year, the data uploaded in InterCatch for 2011 to 2014 were based on the new methodology. For several stocks, the new estimates were considered adequate and are now used for the assessment. For the stocks of southern hake and northern anglerfish (L. piscatorius or L. budegassa) however, some important discrepancies have been noted for 2011 and 2012, the years for which both methods have been used. In the case of southern hake, the difference in landings is considered unrealistic by the experts from the working group while for anglerfish, the new method leads to an important change in the split of the total landing into the two species. Therefore, for those three stocks, the WG decided not to use this data (the 2011 and 2012 landings) until details of the sampling used and the effects of the new method are clarified.

### 1.9 Unallocated landings

For some stocks, some landings were uploaded into InterCatch as "Unreported". Those data were uploaded on a year basis, without any allocation to a specific country and trimester. For some stocks, it was necessary to split the data by trimester to get the best possible assessment of the stock status. The group recommends that next year this data be uploaded at the requested level of aggregation.

### 1.10 Use of InterCatch by WGBIE

Some progress has been made by the group with regards to the use of InterCatch. One stock is using exclusively InterCatch as a tool to compute the model entry files and several stocks are partly using InterCatch in this process. To facilitate the stock coordinators' work in relation to data availability in IC, the WG suggested that once the data from one country has been uploaded and is complete, it would be useful to inform them. This could be done by giving the possibility to the data providers, to acknowledge that their data upload in IC has been completed and by sending an automatic email to the stock coordinators.

### 1.11 Stock annexes

All stocks assessed by this WG have a stock annex.

### 1.12 Proposals for future benchmarks

The following table summarises WGBIE proposals for short and long-term benchmarking.

| Assement | Latest <br> status | Benchmark <br> next year | Planning <br> Year +2 | Comments |  |
| :--- | :--- | :--- | :--- | :--- | :--- |
| Name |  |  | Data |  |  |
| Anglerfish <br> (Lophius <br> budegassa) in <br> Divisions VIIb-k <br> and VIIIa,b,d | Update | WKFLAT | End of 2016 | compilation <br> and length <br> based model | All Anglerfish |
| if possible | together |  |  |  |  |

### 1.12.1 Benchmark planning

The WG reviewed the situation this year and decided to go ahead with the benchmarks proposed for 2016. The ICES benchmark preparation tables by stock were reviewed during the WG meeting. The WG indentified potential directions of solution to improve the assessments of those stocks without deciding yet on any preferred options. They include the use of Under Water TV surveys for the stocks of Nephrops in Gulf of Cadiz (FU 30) and in the Bay of Biscay (FU 23-24) and the use of a survey index to estimates the abundance for the stock of Nephrops in South-West and South Portugal (FU 28-29). A preliminary time table for a data analysis workshop and the benchmark workshop has been proposed. Given the data constraints it appears that the end of 2016 would be the best timing for the benchmark workshop. It was however not possible during the WG to make proposal for external experts. The updated tables and relevant comments regarding the 2015 benchmarks are included in Annex 06 ("Benchmark planning for 2016").

### 1.12.2 Longer-term benchmark planning

WGBIE is also proposing longer term benchmarks and issues that should be addressed in the next round of benchmarks have been listed, even though they are several years in the future. Several benchmarks are thus proposed :
a) For 2017, the group proposed a benchmark for all anglerfish (Lophius piscatorius and L. budegassa) stocks assessed by WGBIE, preferably in conjunction with the anglerfish stocks in Division IIIa, Subarea IV, VI from the other ICES EWG WGCSE, to address issues related to biology of the species (growth and maturity), compilation of data on discards, commercial tunning series, survey abundance/biomass indices and to develop quantitative stock assessment methods. It was agreed during the WG that ICES will launch a data-call on historical series of discards for the northern stocks next fall and that a scoping meeting will be organised for the beginning of 2016 to assess the availability and quality of the data and start preparing for a benchmark later in the year, 2016, or early in 2017.
b) For the stock of megrim (Lepidorhombus whiffiagonis) in Divisions VIIb-k and VIIIa,b,d the WG proposes an inter-benchmark before the end of 2015 to update the assessment model in order to incorporate missing discard data and develop a projection framework based on the output of the Bayesien assessment model specifically developed for that species.
c) For the stock of sea bass in Subarea VIII, the WG proposes a benchmark in conjunction with the stock of sea bass in Divisions IVbc and VIIa,d-h in order to develop an assessment for the Bay of Biscay stock and investigate the possibility to carry out a joint assessment (possibly spatial) with the stock of sea bass in Divisions IVbc and VIIa,d-h.

### 1.13 Mixed Fisheries considerations

No progress has been made on the development of a mixed-fishery analysis since last year. The WG notes however that the Working Group on Mixed Fisheries Advice that will meet from 25-29 May will update the Iberian mixed fisheries analysis carried out in 2013. The WG also notes that mixed fishery analyses of the Bay of Biscay and Iberian waters will be carried out during an STECF meeting scheduled from 25 to 29 May on the development of a multiannual mixed fishery management plan for the South Western Waters (EWG 15-04)

### 1.14 Assessment and forecast auditing process

This year WGBIE has carried out internally an audit of individual assessments and forecasts. WGBIE stocks subjected to review are shown in the table below. Following a template provided by ICES secretariat, the choice of assessment model, the model configuration and the data used in the assessments have been checked against the corresponding settings described in the Stock Annex. Not all audit could be completed by the end of the meeting and the remaining stocks were audited after the meeting. No concerns were raised by the auditors.

| Fish Stock | Stock Name | Stock Coord. | Advice | Review |
| :---: | :---: | :---: | :---: | :---: |
| anp-78ab | Anglerfish (L. piscatorius) in Divisions VIIb-k and VIIIa,b | Spain/UK | Update | Ireland |
| anb-78ab | Anglerfish (Lophius budegassa) in Divisions VIIb-k and VIIIa,b | Spain/UK | Update | Ireland |
| anb-8c9a | Anglerfish (Lophius budegassa) in Divisions VIIIc and IXa | Portugal | Update | Spain |
| anp-8c9a | Anglerfish (L. piscatorius) in Divisions VIIIc and IXa | Spain | Update | UK (EW) |
| hke-nrtn | Hake in Division IIIa, Subareas IV, VI and VII and Divisions VIIIa,b,d (Northern stock); | Spain | Update | France |
| hke-soth | Hake in Division VIIIc and IXa (Southern stock); | Spain | Update | France |
| mgb-8c9a | Megrim (Lepidorhombus boscii) in Divisions VIIIc and IXa | Spain | Update | France |
| mgw-8c9a | Megrim (Lepidorhombus whiffiagonis) in Divisions VIIIc and IXa | Spain | Update | Portugal |
| mgw-78 | Megrim (L. whiffiagonis) in Subarea VII \& Divisions VIIIa,b,d,e | Spain | Update | Spain |
| sol-bisc | Sole in Divisions VIIIa,b,d (Bay of Biscay) | France | Update | Portugal |
| nep-2324 | Nephrops in Divisions VIIIa,b (Bay of Biscay, FU 23, 24) | France | Biennial 1st year | UK (EW) |
| nep-25 | Nephrops in North Galicia (FU 25) | Spain | Biennial 1st year | France |
| nep-31 | Nephrops in the Cantabrian Sea (FU 31) | Spain | Biennial 1st year | France |
| nep-2627 | Nephrops in West Galicia and North Portugal (FU 2627) | Portugal | Biennial <br> 1st year | Spain |
| nep-2829 | Nephrops in South-West and South Portugal (FU 2829) | Portugal | Biennial <br> 1st year | France |
| nep-30 | Nephrops in Gulf of Cadiz (FU 30) | Spain/Portugal | Biennial <br> 1st year | France |

### 1.15 Ecosystem overviews

Iñigo Martínez (ICES) requested a review of the draft report "Ecosystem Overview", section Bay of Biscay and Iberian waters, to include considerations from WGBIE. WGBIE had a subgroup meeting to discuss this draft. The subgroup decided to collect comments and suggestions from all WGBIE members which are summarized here. The group wants to express recognition to the effort devoted to the development of this document, which is an important contribution to the future of ICES ecosystem advice.

General comments:

- Improve the map 7.1.2 including MPAs, main Atlantic harbours (some are notably missing - e.g. Vigo) and fishing areas. The area drawn as "catchment area" was not well understood by the group, particularly in relation to the source of the information..
- Extend the trophic interaction section on 7.3.1 considering the key species interactions. Some trophic relationships are fairly well known - e.g. predation of hake and other predators on blue whiting and other notable forage fish, the cannibalism among hake and the known prey of some cetacean species. Moreover, other studies of stomach analysis for other species have been published in this area.
- Update the state of the stocks: there have been many changes since 2011.
- Section 7.4 "State" should be more developed.
- Section 7.4.5 "Birds" could be renamed as "Seabirds and Marine Mammals"; and some additional information could be included such as the local or small-scale surveys that were carried out. The only global survey carried out in the region was the SCANS-II in July 2005; however an observer program operates annually in the North and Northwest of the Iberian Peninsula using the PELACUS acoustic survey of the IEO as an observer platform since 2007; an expedition to estimate the abundance of cetaceans took place in oceanic waters of Portugal during the summer of 2011 supported by the Life project MarPro. Other small-scale initiatives in Galicia and Cadiz are also under development.
Selection of ecosystem considerations from single stock WGBIE reports:
- Environmental conditions have a large influence on Bay of Biscay Sole catches of the fixed-net fishery. Those conditions were especially favourable in 2002. Studies in Vilaine Bay showed a significant positive relationship between the fluvial discharges in winter-spring and the size of the local nursery. This localized effect is not apparent for the whole of the Divisions VIIIa,b stock and the impact of this relationship was therefore not taken into account in stock projections.
- Hake is a top predator, its abundance has implications on the survival of its preys, mainly pelagic species such as blue whiting, horse mackerel, sardine, etc. Many predators feed on juvenile hake, including adult hake (cannibalism) and other top predators as small cetaceans.
- Anglerfish are benthic species that occur on muddy and gravel bottoms. The spawning of the Lophius species is very particular, with eggs extruded in a buoyant, gelatinous ribbon. Eggs and larvae drift with ocean currents and juveniles settle on the seabed. This particular spawning strategy leads to highly clumped distributions of eggs and larvae. Oceanographic conditions
can therefore have major impacts on recruitment. Anglerfish are top predators, with a diet that reflects temporal prey availability. Larger fish can migrate over long distances.
- Megrim species generally occur over soft bottoms of the continental shelf. They are common on the outer side of zones with hydrographical instabilities that foster the vertical interchange of organic matter and are missing at the mouth of big rivers. Juveniles of these species feed mostly on detritivore crustaceans inhabiting deep-lying muddy bottoms. Adults of Lepidorhombus boscii feed mainly on crustaceans while L. whiffiagonis are more ichthyophagous and rates of crustacean in diet decrease with fish size. None of the two species represent an important part of the diet for the main fish predators in the area but they are occasionally present in stomach contents of hake, anglerfish and rays. Both species show a gradual bathymetric distribution with larger individuals occupying shallower waters than juveniles.

Nephrops are limited to muddy habitats. Distribution of suitable sediment defines the distribution of the species. Nephrops are sedentary but they can leave their burrows in search of food and for reproduction. Berried Nephrops stay most of the time inside their burrows. Larvae are pelagic for one month after hatching, then after metamorphosis the small Nephrops settle on the sea bed.

## 2 Description of Commercial Fisheries and Research Surveys

### 2.1 Fisheries description

This Section describes the fishery units relevant for the stocks assessed in this WG. Additionally, to facilitate the use of InterCatch, it presents the "fleets" that the WG proposes to use for data submission in InterCatch.

### 2.1.1 Celtic - Biscay Shelf (Subarea VII and Divisions VIIIa,b,d).

The fleets operating in the ICES Subarea VII and Divisions VIIIabd are used in this WG following the Fishery Units (FU) defined by the "ICES Working Group on Fisheries Units in sub-areas VII and VIII" (ICES, 1991):

Under the implementation of the mixed fisheries approach in the ICES WG's new information updating some national fleet segmentations was presented in WGHMM reports in the last few years, from general overviews (ICES, 2004; ICES, 2005) to detailed national descriptions: French fleets (ICES, 2006), Irish fleets (ICES, 2007), and Spanish fleets (ICES, 2008). This new information in relation to the métiers definition did not change the Fishery Units used in the single stock assessments. However, the hierarchical disaggregation of FU into métiers is essential not only for carrying out mixedfisheries assessments, but also for a deeper understanding of the fisheries behaviour.

| FISHERY UNIT | DesCription | SUB-AREA |
| :--- | :--- | :--- |
| FU1 | Long-line in medium to deep water | VII |
| FU2 | Long-line in shallow water | VII |
| FU3 | Gill nets | VII |
| FU4 | Non-Nephrops trawling in medium to deep water | VII |
| FU5 | Non-Nephrops trawling in shallow water | VII |
| FU6 | Beam trawling in shallow water | VII |
| FU8 | Nephrops trawling in medium to deep water | VII |
| FU9 | Nephrops trawling in shallow to medium water | VIII |
| FU10 | Trawling in shallow to medium water | VIII |
| FU12 | Long-line in medium to deep water | VIII |
| FU13 | Gill nets in shallow to medium water | VIII |
| FU14 | Trawling in medium to deep water | VIII |
| FU15 | Miscellaneous | VII \& VIII |
| FU16 | Outsiders | IIIa, IV, V \& VI |
| FU00 | French unknown |  |

The EU Data Collection Framework (DCF; Council Regulation (EC) 199/2008; EC Regulation 665/2008; Decision 2008/949/EC) establishes a framework for the collection of economic, biological and transversal data by Member States. One of the most relevant changes of this new period with respect to the previous Data Collection Regulation (DCR; Reg. (EC) No 1639/2001) has been the inclusion of the ecosystem approach by means of moving from stock-based sampling to métier-based sampling. The new DCF defines the métier as "a group of fishing operations targeting the same species or a similar assemblage of species, using similar gear, during the same period of the year and/or within the same area, and which are characterized by a similar exploitation pattern". Due to the new sampling design, established since 2009, which can affect the fishery data supplied to
this WG, it has been agreed to detail the métiers related with the stocks assessed by this WG, trying to find the correspondence with the Fishing Units.

Data for stock assessment are typically provided to stock coordinators either still according to the old FUs and the traditional tuning fleets or to the DCF métiers. In the case of discards and/or biological data, even though sampling may be done at the DCF métier Level 6, estimates are often re-aggregated to Level 5 due to low sampling levels reached by countries. Thus, this WG agreed to use DCF Level 5 (without mesh size) as the "fleet" level to introduce data in InterCatch. The table below shows the "fleets" to be used for InterCatch and their correspondence with the old Fishery Units and the DCF métiers at Level 6.

| FU | Fleet for InterCatch | DCF METIER (Level 6) | DESCRIPTION | FR | IR | SP | UK |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| FU1 | LLS_DEF | LLS_DEF_0_0_0 | Set longline directed to demersal fish |  |  | X | X |
| FU2 |  |  |  |  |  |  |  |
| FU3 | GNS_DEF | GNS_DEF_100-219_0_0 | Set gillnet directed to demersal fish ( $100-219 \mathrm{~mm}$ ) | X | X | X |  |
| FU4 | OTB_DEF | OTB_DEF_70-99_0_0 | Bottom otter trawl directed to demersal fish ( $70-99 \mathrm{~mm}$ ) |  | X | X | X |
|  |  | OTB_DEF_100-119_0_0 | Bottom otter trawl directed to demersal fish (100-119 mm) |  |  | X | X |

| FU9 | OTB_CRU | OTB_CRU_70-99_0_0 | Bottom otter trawl directed to crustaceans ( $70-99 \mathrm{~mm}$ ) | X | X |  | X |
| FU10 | OTB_DEF |  |  |  |  |  |  |
| FU12 | LLS_DEF | LLS_DEF_0_0_0 | Set longline directed to demersal fish | X |  | X |  |
| FU13 | GNS_DEF | GNS_DEF_45-59_0_0 | Set gillnet directed to demersal fish ( $45-59 \mathrm{~mm}$ ) | X |  |  |  |
|  |  | GNS_DEF_>=100_0_0 | Set gillnet directed to demersal fish (at least 100 mm ) | X |  | X |  |
| FU14 | OTB_DEF | OTB_DEF_>=70_0_0 | Bottom otter trawl directed to demersal fish (at least 70 mm ) | X |  | X |  |
|  | OTB_MCF | OTB_MCF _>=70_0_0 | Bottom otter trawl directed to mixed cephalopods and demersal fish (at least 70 mm ) |  |  | X |  |
|  | OTT_DEF | OTT_DEF _>=70_0_0 | Multi-rig otter trawl directed to demersal fish (at least 70 mm ) | X |  |  |  |
|  | OTB_CRU | OTB_CRU _>=70_0_0 | Bottom otter trawl directed to crustaceans (at least 70 mm ) | X |  |  |  |
|  | OTT_CRU | OTT_CRU _>=70_0_0 | Multi-rig otter trawl directed to crustaceans (at least 70 mm ) | X |  |  |  |
|  | OTB_MPD | OTB_MPD _>=70_0_0 | Bottom otter trawl directed to mixed pelagic and demersal fish (at least 70 mm ) |  |  | X |  |
|  | PTB_DEF | PTB_DEF _>=70_0_0 | Bottom pair trawl directed to demersal fish (at least 70 mm ) |  |  | X |  |
| FU15 | SSC_DEF |  | Fly shooting seine directed to demersal fish |  |  |  |  |
| FU16 | OTB_DEF | OTB_DEF _100-119_0_0 | Bottom otter trawl directed to demersal fish (100-119 mm) | X |  | X | X |
|  | LLS_DEF | LLS_DEF _0_0_0 | Set longline directed to demersal fish |  |  | X |  |
|  | SSC_DEF |  | Fly shooting seine directed to demersal fish |  |  |  |  |
| FU00 | PTM_DEF |  | Midwater pair trawl directed to demersal fish |  |  |  |  |

For the Bay of Biscay sole stock, the correspondence with DCF métiers is somewhat complicated because the fleets used are:

Inshore-gillnets (French gillnetters with length $<12 \mathrm{~m}$ ) (GNx or GTx)
Offshore-gillnets (French gillnetters with length > 12 m ) (GNx or GTx)
Inshore-trawlers (French trawlers with length $<12 \mathrm{~m}$ ) (OTx, TBx, PTx)

Offshore-trawlers (French trawlers with length > 12 m )
In other words, the fleets used correspond to netters and trawlers fishing for sole in the Bay of Biscay, grouped according to vessel length.

### 2.1.2 Atlantic Iberian Peninsula Shelf (Divisions VIIIc and IXa).

The Fishery Units operating in the Atlantic Iberian Peninsula waters were described originally in the report of the "Southern hake task force" meeting (STECF, 1994), and have been used for several years in this WG as follows:

| Country | Fishery Unit | Description |
| :---: | :---: | :---: |
| Spain | Small Gillnet | Gillnet fleet using "beta" gear ( 60 mm mesh size) for targeting hake in Divisions VIIIc and IXa North |
|  | Gillnet | Gillnet fleet using "volanta" gear ( 90 mm mesh size) for targeting hake in Division VIIIc |
|  |  | Gillnet fleet using "rasco"gear ( 280 mm mesh size) for targeting anglerfish in Division VIIIc |
|  | Long Line | Long line fleet targeting a variety of species (hake, great fork beard, conger) in Division VIIIc |
|  | Northern Artisanal | Miscellaneous fleet exploiting a variety of species in Divisions VIIIc and IXa North |
|  | Southern Artisanal | Miscellaneous fleet exploiting a variety of species in Division IXa South (Gulf of Cádiz) |
|  | Northern Trawl | Miscellaneous fleet operating in Divisions VIIIc and IXa North composed of bottom pair trawlers targeting blue whiting and hake ( 55 mm mesh size, and 25 m of vertical opening); and two types of bottom otter trawlers ( 70 mm mesh size): trawlers using the "baca" gear (1.5 of vertical opening) targeting hake, anglerfish, megrim and Nephrops, and trawlers using "jurelera" (often referred to as "HVO", high vertical opening, in the present report) gear ( $>5 \mathrm{~m}$ of vertical opening) targeting mackerel and horse mackerel. |
|  | Southern Trawl | Bottom otter trawlers operating in Division IXa South (Gulf of Cádiz) exploiting a variety of species (sparids, cephalopods, sole, hake, horse mackerel, blue whiting, shrimp, Norway lobster). |
| Portugal | Artisanal | Miscellaneous fleet with two components (inshore and offshore) operating in Portuguese waters of Division IXa involving gillnet ( 80 mm mesh size), trammel ( 100 mm mesh size), long line and other gears. Species caught: hake, octopus, pout, horse mackerel and others |
|  | Trawl | Trawl fleet opertaing in Portuguese waters of Division IXa copmpounded by bottom otter trawlers targeting crustaceans ( 55 mesh size), and bottom oter trawlers targeting different species of fish ( 65 mm mesh size). |

The Spanish and Portuguese fleets operating in the Atlantic Iberian Peninsula shelf were segmented into métiers under the EU project IBERMIX (DG FISH/2004/03-33), and the results were described in Section 2 of the 2007 WGHMM report (ICES, 2007).

The correspondence between Fishing Units and DCF métiers has been also compiled for the southern stocks fleets and is presented in the following table. As for the CelticBiscay shelf, sampling inconsistencies among biological and commercial data make the use of the DCF Level 5 preferable to introduce Iberian data in InterCatch. This re-aggregation affects the Spanish gillnet operating in the Northern Spanish waters, because
the set gillnet ("beta") directed to hake (GNS_DEF_60-79_0_0) and the set gillnet ("volanta") also targeting hake (GNS_DEF_80-99_0_0) must be sampled together. It must taken into account that the set gillnet using more than 280 mm mesh size (GNS_DEF_280_0_0) targets mostly anglerfish and cannot be distinguished at Level 5 (the level proposed for the InterCatch fleets) from the two gillnet métiers previously mentioned (which are directly mainly to hake). So a revision of the current InterCatch fleet proposal may be required in this case (to be decided by the WG by mid-September, as stated at the start of Section 2.1).

| COUNTRY | FU | Fleet for InterCatch | METIERS (Level 6) | DESCRIPTION (mesh size in brackets) | SP | PT |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: |
|  | Gillnet |  | GNS_DEF_80-99_0_0 | Set gillnet directed to demersal species (80-99 mm ) | X |  |
|  |  | GNS_DEF | GNS_DEF_280_0_0 | Set gillnet directed to demersal species (at least 280 mm ) | X |  |

### 2.2 Description of surveys

This section gives a brief description of the surveys referred to in this WG report. The surveys are listed in the following table, including the acronym used by WGHMM in 2010, the DCF acronym and the new ICES survey acronym which will be used throughout this WG report and Stock Annexes. The new survey acronyms used this year were provided by ICES Secretariat, aiming for consistency across all ICES Expert Groups. When ICES Secretariat has not included a survey in the list for which it has provided acronyms, the WGHMM 2010 acronym will remain in use.

| Survey | WGHMM 2010 acronym | DCF acronym | ICES survey acronym as of 2011 |
| :---: | :---: | :---: | :---: |
| Spanish groundfish survey quarter 4 | SP-GFS | IBTS-EA-4Q | SpGFS-WIBTS-Q4 |
| Spanish Porcupine groundfish survey | SP-PGFS | IBTS-EA | SpPGFS-WIBTS-Q4 |
| Spanish Cadiz groundfish survey - Autumn | SP-GFS-caut |  | SPGFS-caut-WIBTS-Q4 |
| Spanish Cadiz groundfish survey - Spring | SP-GFS-cspr |  | SPGFS-cspr-WIBTS-Q1 |
| Portuguese groundfish survey <br> - October | P-GFS-oct | IBTS-EA-4Q | PtGFS-WIBTS-Q4 |

| English fisheries science partnership survey | EW-FSP |  | FSP-Eng-Monk |
| Irish groundfish survey | IGFS | IBTS-EA-4Q | IGFS-WIBTS-Q4 |

A brief description of each survey follows. A general map identifying survey areas can be found in ICES IBTS WG reports.

### 2.2.1 Spanish groundfish survey (SpGFS-WIBTS-Q4)

The SpGFS-WIBTS-Q4 covers the northern Spanish shelf comprised in ICES Division VIIIc and the northern part of IXa, including the Cantabrian Sea and off Galicia waters.

It is a bottom trawl survey that aims to collect data on the distribution, relative abundance and biology of commercial fish species such as hake, monkfish and white anglerfish, megrim, four-spot megrim, blue whiting and horse mackerel. Abundance indices are estimated by length and in some cases by age, with indices also estimated for Nephrops, and data collected for other demersal fish and invertebrates. The survey is ca. 120 hauls and is from $30-800 \mathrm{~m}$ depths, usually starts at the end of the $3^{\text {rd }}$ quarter (September) and finishes in the $4^{\text {th }}$ quarter.

### 2.2.2 Spanish Porcupine groundfish survey (SpPGFS-WIBTS-Q4)

The SpPGFS-WIBTS-Q4 occurs at the end of the $3^{\text {rd }}$ quarter (September) and start of the $4^{\text {th }}$ quarter. It is a bottom trawl survey that aims to collect data on the distribution, relative abundance and biology of commercial fish in ICES Division VIIb-k, which corresponds to the Porcupine Bank and the adjacent area in western Irish waters between $180-800 \mathrm{~m}$. The survey area covers $45880 \mathrm{Km}^{2}$ and approximately 80 hauls per year are carried out.

### 2.2.3 Cadiz groundfish surveys - Spring (SPGFS-cspr-WIBTS-Q1) and Autumn (SPGFS-caut-WIBTS-Q4)

The bottom trawl surveys SPGFS-cspr-WIBTS-Q1 and SPGFS-caut-WIBTS-Q4 occur in the southern part of ICES Division IXa, the Gulf of Cádiz, and collect data on the distribution, relative abundance, and biology of commercial fish species. The area covered is $7224 \mathrm{Km}^{2}$ and extends from 15-800m. The primary species of interest are hake, horse mackerel, wedge sole, sea breams, mackerel and Spanish mackerel. Data and abundance indices are also collected and estimated for other demersal fish species and invertebrates such as rose and red shrimps, Nephrops and cephalopod molluscs.

### 2.2.4 Portuguese groundfish survey October (PtGFS-WIBTS-Q4)

PtGFS-WIBTS-Q4 extends from latitude $41^{\circ} 20^{\prime} \mathrm{N}$ to $36^{\circ} 30^{\prime} \mathrm{N}$ (ICES Div. IXa) and from 20 to 500 m depth. The survey takes place in Autumn. The main objectives of the survey is to estimate the abundance and study the distribution of the most important commercial species in the Portuguese trawl fishery ( hake, horse mackerel, blue whiting, seabream and Nephrops), mainly to monitor the abundance and distribution of hake and horse mackerel recruitment. The surveys aim to carry out ca. 90 stations per year.

### 2.2.5 Portuguese crustacean trawl survey / Nephrops TV survey offshore Portugal (PT-CTS (UWTV (FU 28-29))

The PT-CTS (UWTV (FU 28-29)) survey is carried out in May-July and covers the southwest coast (Alentejo or FU 28) and the south coast (Algarve or FU 29). The main objectives are to estimate the abundance, to study the distribution and the biological characteristics of the main crustacean species, namely Nephrops norvegicus (Norway lobster), Parapenaeus longirostris (rose shrimp) and Aristeus antennatus (red shrimp). The average number of stations in the period 1997-2004 was 60 . Sediment samples have been collected since 2005 with the aim to study the characteristics of the Nephrops fishing grounds. In 2008 and 2009, the crustacean trawl survey conducted in Functional Units 28 and 29, was combined with an experimental video sampling.

### 2.2.6 Portuguese winter groundfish survey/Western IBTS 1 st quarter (PtGFS-WIBTS-Q1)

The PtGFS-WIBTS-Q1survey has been carried out along the Portuguese continental waters from latitude $41^{\circ} 20^{\prime} \mathrm{N}$ to $36^{\circ} 30^{\prime} \mathrm{N}$ (ICES Div. IXa) and from 20 to 500 m depth. The winter groundfish survey plan comprises 75 fishing stations, 66 at fixed positions and 9 at random. The main aim of the survey is to estimate spawning biomass of hake.

### 2.2.7 French EVHOE groundfish survey (EVHOE-WIBTS-Q4)

The EVHOE-WIBTS-Q4 survey covers the Celtic Sea with ICES Divisions VIIfghj, and the French part of the Bay of Biscay in divisions VIIIab. The survey is conducted from 15 to 600 m depths, usually in the fourth quarter, starting at the end of the October. The primary species of interest are hake, monkfish, anglerfish, megrim, cod, haddock and whiting, with data also collected for all other demersal and pelagic fish. The sampling strategy is stratified random allocation, the number of set per stratum based on the 4 most important commercial species (hake, monkfishes and megrim) leaving at least two stations per stratum and 140 valid tows are planned every year although this number is dependent on available sea time.

### 2.2.8 French RESSGASC groundfish survey (RESSGASC)

The RESSGASC survey was conducted in the Bay of Biscay from 1978 to 2002. Over the years 1978-1997 the survey was conducted with quarterly periodicity. It was conducted twice a year after that (in Spring and Autumn). Survey data prior to 1987 are normally excluded from the time series, since there was a change of vessel at that time.

### 2.2.9 French Bay of Biscay sole beam trawl survey (ORHAGO)

The ORHAGO survey was launched in 2007, with the aim of producing an abundance index and biological parameters such as length distribution for the Bay of Biscay sole. It is usually carried out in November, with approximately 23 days of duration and sampling 70-80 stations. It uses beam trawl gear and is coordinated by the ICES WGBEAM.

### 2.2.10 French Nephrops survey in the Bay of Biscay (LANGOLF)

This survey commenced in 2006 specifically for providing abundance indices of Nephrops in the Bay of Biscay. It is carried out on the area of the Central Mud Bank of the Bay of Biscay (ca. $11680 \mathrm{~km}^{2}$ ), in the second quarter (May apart from the $1^{\text {st }}$ year when the survey occurred in April), using twin trawl, with hours of trawling around dawn and dusk. The whole mud bank is divided to five sedimentary strata and the sampling allocation combines the surface by stratum and the fishing effort concentration. 70-80 experimental hauls are carried out by year. Since the IBP Nephrops 2012, this survey is included as tuning series in the stock assessment.

### 2.2.11 UK west coast groundfish survey (UK-WCGFS)

This survey, which ended in 2004, was conducted in March in the Celtic sea with ca. 62 hauls. It does not include the 0 -age group with one of the primary aims to investigate the 1 and 2 age groups. Numbers at age for this abundance index are estimated from length compositions using a mixed distribution by statistical method.

### 2.2.12 English fisheries science partnership survey (FSP-Eng-Monk)

The FSP-Eng-Monk survey, part of the English fisheries science partnership programme, has been carried out every year since 2003 with 208 valid hauls in 2010. The aims of the survey are to investigate abundance and size composition of anglerfish on the main UK anglerfish fishing grounds off the southwest coast of England within ICES subdivisions VIIe-h.

### 2.2.13 English Western English Channel Beam Trawl Survey

Since 1989 the survey has remained relatively unchanged, apart from small adjustments to the position of individual hauls to provide an improved spacing. In 1995, two inshore tows in shallow water ( $8-15 \mathrm{~m}$ ) were introduced. The survey now consists of 58 tows of 30 minutes duration, with a towing speed or 4 knots in an area within 35 miles radius of Start Point. The objective is to provide indices of abundance, which are independent of commercial fisheries, of all age groups of sole and plaice on the western Channel grounds, and an index of recruitment of young (1-3 year-old) sole prior to full recruitment to the fishery.

### 2.2.14 English Bottom Trawl Survey

This bottom trawl survey covered the Irish, Celtic Sea and Western English Channel but was it discontinued in 2004.

### 2.2.15 Irish groundfish survey (IGFS-WIBTS-Q4)

The IGFS-WIBTS-Q4 is carried out in 4th quarter in divisions VIa, VIIbcgj, though only part of VIa and the border of Division VIIc, in depths of $30-600 \mathrm{~m}$. The annual target is 170 valid tows of 30 minute duration which are carried out in daylight hours at a speed of 4 knots. Data is collected on the distribution, relative abundance and biological parameters of a large range of commercial fish such as haddock, whiting, plaice and sole with survey data provided also for cod, white and black anglerfish, megrim, lemon sole, hake, saithe, ling, blue whiting and a number of elasmobranchs as well as several pelagics (herring, horse mackerel and mackerel).

## 3 Anglerfish (Lophius piscatorius and Lophius budegassa) in Divisions VIIb-k and VIIIa,b,d

There has been no accepted assessment for either L. piscatorius or L. budegassa since 2007. The Working Group in 2007 found that the input data showed deficiencies, especially as discarding was known to be increasing and that ageing problems had become more obvious. The stock went through a benchmark process during 2012 (WKFLAT 2012) but no analytical assessment was found acceptable.

## L. piscatorius and L. budegassa:

Type of assessment in 2015: Same Advice as Last Year (SALY).
Data revisions this year: 2013 Spanish landings were revised.

## Review Group issues:

The RG noted that unless discarding of small fish is taken into account, it may be difficult to develop a length-based analytical assessment for this stock.

### 3.1 General

### 3.1.1 Summary of ICES advice for 2015 and management for 2014 and 2015

## ICES advice for 2015

## Lophius piscatorius

ICES advises that when the precautionary approach is applied, landings in 2016 should be no more than 10757 tonnes. ICES cannot quantify the corresponding total catches.

## Lophius budegassa

ICES advises that when the precautionary approach is applied, landings in 2016 should be no more than 26691 tonnes. ICES cannot quantify the corresponding total catches.

Management of the two anglerfish species under a combined TAC prevents effective control of the single-species exploitation rates and could potentially lead to overexploitation of either species

## Management applicable for 2014 and 2015

The TAC applied to both species and including Division VIIa was set at 42496 t for 2014 and for 2015.

Since $1^{\text {st }}$ February 2006 a ban on gillnet at depth greater than 200 m was set in Subareas VI a,b and VIIb,c,j,k.

### 3.1.2 Landings

Landings have increased since 2000 and have fluctuated around 33000 t since 2003. The landings of both species combined were estimated to be 28880 t in 2010, 28357 t in 2011 and 33373 t in 2012. Estimated landings of 36855 t in 2013 are at the highest level over the last 10 years and the fourth highest of the time series, landings of 36200 in 2014, are close to levels seen in 2013 (Table 3.1-1).

There was a revision for the Spanish data for the years 2011 to 2012 due to the new method in estimating the landings. Although the total landings for the two species combined are similar to the previous estimates this has had an impact on how the species are split for assessment purposes. Therefore the WG decided not to use this data until details of the sampling used and the effects of the new method are clarified.

### 3.1.3 Discards

Estimates of discards have been carried out and new data have been made available to the working group by all countries for the first time. This information shows that an increasing proportion of small fish of both species are caught and discarded. After an extensive analysis of discard data by WKFLAT 2012, discard estimates were considered not to be precise with a high level of uncertainty due to raising methods using very limited sampling, therefore the group decided not to use the discard estimates in the assessment or for advice purposes.

Table 3.1-1. Anglerfish in Divisions VIIb-k and VIIIa,b,d -Total landings from 1984 to 2014 - Working Group estimates

### 3.2 Anglerfish (L. piscatorius) in Divisions VIIb-k and VIIIa,b,d

### 3.2.1 Data

### 3.2.1.1 Commercial Catch

The Working Group estimates of landings of L. piscatorius by fishery unit (defined in Section 2 of the report) are given in Table 3.2-1 Lophius piscatorius in Divisions VIIb-k and VIIIa,b,d - Landings in tonnes by Fishery Unit.

The landings have declined steadily from 23666 t in 1986 to 12766 t in 1992, then increased to 22162 t in 1996 and declined to 13941 t in 2000. The landings have increased since then reaching the maximum of the time series in 2007 ( 28977 t ). The 2008 value shows a $16 \%$ drop to 24376 t . In 2009 the decreasing trend continued with a $24 \%$ drop ( 18844 t ) and in 2010 landings recovered to historic mean levels at 19521 t .
The 2011 landings started an increasing trend with landings estimates of 20370 t . The 2012 landings showed a further increase to 24409 t . In 2013 a slight decrease of the landings gave a figure of 23759 t . In 2014 the preliminary data estimated the landings of L. piscatorius to be 25328 t .

### 3.2.1.2 Commercial LPUE

Effort and LPUE data for the three Spanish fleets and English FU6 were available up to 2014 (Table 3.2-2 L. piscatorius in Divisions VIIb-k and VIIIa,b,d- Effort and LPUE data and Figure 3.2-1 L. piscatorius in Divisions VIIb-k and VIIIa,b,d- Effort and LPUE data). Fishing effort for most fleets showed a decrease until the mid 1990's. Effort remained relatively stable thereafter, from 2011 to 2014 a sharp decrease in SP-VIGO7 ( $66 \%$ reduction) and SP-CORUTR7 ( $83 \%$ reduction) was recorded maybe due to the vessels with in the fleet landing under a different country but operating as in previous years.
All the commercial LPUE series decreased steadily until 1992. Since then, they have increased up to 2007 except for the 2 BAKA fleets. Most showed a decline in 2008. In 2009 and 2010 EW-FU06 and both BAKA fleets showed an increasing trend but SPVIGO7 and SP-CORUTR7 showed a decreasing one. In 2011 all available fleets showed an increasing trend that continues in 2012 for all fleets with the exception of EW-FU06. In 2013 Spanish fleets showed the second highest LPUE of the time series and SPVIGO7, SP-CORUTR7 and EW-FU06 continued decreasing but remaining the fifth highest of the time series. In 2014 SP-VIGO7, SP-CORUTR7 and EW-FU06 showed the highest LPUE's of the time-series.

### 3.2.1.3 Surveys data

### 3.2.1.3.1 The French EVHOE-WIBTS-Q4 survey

This survey covers the highest proportion of the area of stock distribution. Standardised biomass and abundance indices are given inFigure 3.2-2 L. piscatorius in Divisions VIIb-k and VIIIa,b,d- Time-series of the EVHOE-WIBTS-Q4 survey indices Kg (left) and Nb (right) per 30 minutes tow from 1997 to 2014and the length distributions in Figure 3.2-3 - L. piscatorius in Divisions VIIb-k and VIIIa,b,d. Time-series of the EVHOE-WIBTS-Q4 Length distributions in Nb per 30 minutes tow from 1997 to 2014.

The biomass indices show a continuous increase from 2000 to 2007 and a decrease thereafter, with the 2010 index value in between those from 2000 and 2001. In 2011 the
indices were as high as the 2005 value and the 2012 value recorded the historical maximum, in 2013 the index was similar to 2011 level and 2014 index similar to 2010 level. Abundance in numbers shows four peaks in 2001, 2002, 2004 and to a lesser extent 2008. Since 2008 the abundance in numbers remains stable. In 2013 and 2014 the abundance in number showed one of the lowest levels in the 2001 - 2014 period.
The length distribution shows that these peaks in numbers of abundance correspond to strong incoming year-classes that can be tracked from year to year with modes between 10-25 cm for the first age group (in 2001, 2002, 2004, 2008, 2009, 2010,2011 and 2014), $25-45$ for the second ( $2002,2003,2005,2009,2010,2011$ and 2014) and $45-55$ for the third (2003, 2004, 2005, 2010 and 2011), although, the third mode is not as clearly defined.

These year classes are now still present in the recent survey catches at larger sizes and account for the higher biomass index. The length distribution in 2009 and 2010 indicates two good recruitments at the level seen in 2008, although not as strong as in 2001, 2002 and 2004. 2011 and 2012 recruitment seems to be at medium levels. 2013 recruitment is the second lowest since 2001. 2014 recruitment is similar to the 2008 - 2010 levels.

In Figure 3.2-4 and, Figure 3.2-5 the distribution of recruits (identified as individuals of less than 23 cm ) show that contrasting with the years 2001, 2002 and 2004 where the recruits were found in both Celtic Sea and Bay of Biscay areas along the shelf, the recruits were found almost only south of the Celtic Sea and in the Bay of Biscay in 2008 and 2009. The results from 2010 to 2012 show a uniform distribution of recruits through the sampling area of the survey. 2013 shows a uniform distribution with low levels of recruitment. In 2014 the recruitment was found only in the Bay of Biscay area.

### 3.2.1.3.2 The Spanish Porcupine Groundfish Survey (SPPGFS (WIBTS-Q4))

This survey was initiated in 2001 and covers the Porcupine Bank. Standardised biomass and abundance indices are given in Figure 3.2-6 and the length distributions in Figure 3.2-7. Although covering a small area of the total stock distribution, similar pulses of recruitment are detected in 2001 and to a lower extent in the years 2002 to 2004. In 2010 a recruitment level similar to 2002-2004 was found. In 2011 the recruitment level was low and in 2012 the recruitment returned to medium values. In 2013 a revision of the indices for the period 2003-2012 was presented with no effects in the trends of the series. 2013 values are the second higher of the series for both biomass and abundance indices. 2014 values are the maximum of the series for both indices.

### 3.2.1.3.3 The Irish Groundfish Survey (IGFS-WIBTS-Q4)

Abundance indices in numbers per ten square kilometres from this survey are given in
Table 3.2-3 and length distributions from 2001 to 2014 in Figure 3.2-8 - L. piscatorius in Divisions VIIb-k and VIIIa,b,d- Time-series of the IGFS-WIBTS-Q4 Length distributions in Nb per $10 \mathrm{Km}^{2}$ from 2001 to 2014. The index shows the same drop as the EVHOE-WIBTS-Q4 and the SPPGFS (WIBTS-Q4) after the peak in 2004. The 2009 index showed a recovery in abundance, although it was still lower than the 2005 value. In 2010 and 2011 a value close to the 2004 maximum has been found. In 2012 a value similar to the 2009 medium level was recorded. In 2013 the value continued in medium levels but higher than in 2012. In 2014 the index shows the maximum of the series with $114.9 \mathrm{Nb} / 10 \mathrm{Km}^{2}$, and the length distribution of the catch shows the highest recruitment of the series.

### 3.2.2 Conclusion

LPUE's and survey data (biomass, abundance indices and length distributions) give indication that the biomass has been increasing as a consequence of the good recruitment observed in 2001, 2002 and 2004 and has stabilised in recent years. There is evidence of good recruitments in 2008, 2009, 2010 and 2011. 2008 and 2009 recruitments have entered the fishery giving one of the higher yields of the time series. Recruitment in 2012 and 2013 was lower than previous years and this could have implications for the total biomass of the stock in the future but if the very high recruitment of 2014 is confirmed this could offset the expected reduction in biomass.

Preliminary information on discards shows that an increasing proportion of small fish are caught and discarded (WKFLAT12) and results from this year's data available for the first time to the working group shows that around nine percent of the catch is discarded. Due to the low levels of sampling and the uncertainties in the precision of the estimates the group recommends that the discard estimates are not used in the assessment or for advice purposes.

As discard information has been made available to the working group further years submissions will allow for a more extensive analysis of the estimates so that catch information can be presented with confidence

With the discarding of small fish caught, measures should be taken to ensure good survival of the recent recruits such as spatial and technical measures.

The Working Group concludes that in view of the available data, continuing fishing at present level should not harm the stock.

### 3.2.3 Comments on the assessment

Data from surveys tracking recent good recruitment give scope for the use of length based models for assessment, growth studies and ageing validation that should be initiated as soon as possible.

Table 3.2-1 Lophius piscatorius in Divisions VIIb-k and VIIIa,b,d - Landings in tonnes by Fishery Unit.

### 3.3 Anglerfish (L. budegassa) in Divisions VIIb-k and VIIIa,b,d

### 3.3.1 Data

### 3.3.1.1 Commercial Catch

The Working Group estimates of landings of L. budegassa by fishery unit (defined in Section 2) are given in Table 3.3-1.

The landings have fluctuated over the studied period between 5720 t to 12789 t with a succession of high (1989-1991, 1998 and 2009-2014) and low values (1994, 2001 and 2006). The total estimated landings dropped from 2003 to 2006 and since then have risen to the highest of the time-series with an estimated landings value of 12789 t in 2013. Landings in 2014 dropped to 10872 t but is still the second highest of the timeseries.

### 3.3.1.2 Commercial Effort and LPUE

Effort and LPUE data were available in 2014 for the three Spanish fleets, and for the English EW-FU06 (Table 3.3-2 and figure 3.3-1). Fishing effort for most fleets shows a decrease until the early 2000's. Effort remained relatively stable thereafter, with the exception of SP-BAKON7 which disappeared in 2009 but reappeared again in 2010 with 2008 effort levels and disappeared thereafter. From 2011 to 2013 a sharp decrease in SP-VIGO7 (41 \% reduction) and SP-CORUTR7 (77 \% reduction) was recorded and the decline continues, this may be due to the vessels with in the fleet landing under a different flag but operating as in previous years.

LPUEs have fluctuated over the time-series with increasing trends since 2006 and conflicting trends for the most recent period. In 2012 the LPUE for the SP-VIGO7 fleet was the highest of the time-series, the other fleets SP-CORUTR7 and SP-BAKON8 showed their series maximum in 2013 and the EW-FU06 in 2014.

### 3.3.1.3 Surveys data

### 3.3.1.3.1 The French EVHOE-WIBTS-Q4 survey

This survey covers the highest proportion of the area of stock distribution. Standardised biomass and abundance indices are given in Figure 3.3-1. The biomass index shows patterns of increase and decrease over the time-series, with a continuous increase from 2005 to its maximum value in 2008 followed again by a decrease to 20032005 levels. The most recent year continues the decline in biomass, since 2012, to just above the average of the time series. The abundance index shows a similar pattern reach its highest values in the time series in 2008 and 2013. In 2009 and 2010 the indices returned to 2004-2005 levels, the most recent year shows a decline in abundance but again remains above the mean level for the time-series.
The length distributions (Figure 3.3-2.) show that the abovementioned results correspond to strong incoming year-classes from 2004 until 2008 that can be tracked from year to year with modes between 10-17 cm for the first age group (since 2004), 18 - 32 for the second (2005, 2007 and 2008), 33-45 for the third and 50-55 for the fourth (more obvious in 2008).
For 2009 the length distribution does not show a strong signal of recruitment nor can the signal from 2008's strong recruitment be followed. 2010 shows a medium level recruitment and 2011, 2012 and 2013 gives the strongest signals of the time series for recruits.

The localisation of juveniles (individuals less than 16 cm ) caught during the survey from 1997 to 2008 show two nursery areas one in the western Celtic Sea and another in the north-western area of the Bay of Biscay (Figure 3.3-3Error! Reference source not found. and Figure 3.3-4), in some of the years, juveniles are also found in a more southern area of the Bay of Biscay in deeper waters. In 2010 to 2014 the normal pattern was found again with a more confined distribution in the western Celtic Sea.

### 3.3.1.3.2 The English Fisheries Science Partnership survey.

This survey samples a fraction of each of the areas VIIe, VIIf, VIIg and VIIh and was discontinued in 2013. The survey covers a restricted area of the species distribution but the pulses of recruitment observed in the EVHOE-WIBTS-Q4 surveys are also present in the FSP-ENG-MONK survey in the following year. Length distribution of L. budegassa catches are available and presented in Figure 3.3-5.

For 2009 the English survey has recorded its historical maximum for recruitment and the good recruitment can be tracked from 2008. In 2010 to 2012 the recruitment returned to low levels and the good recruitments from 2008 and 2009 can be followed.

The first mode of this survey's length distributions tends to be found at slightly larger lengths than the first mode of the EVHOE-WIBTS-Q4 survey and strong recruitment signal according to EVHOE-WIBTS-Q4 in a given year tends to be followed by a strong signal around $16-28 \mathrm{~cm}$ for this survey in the following year. However the strong incoming year-class from the EVHOE-WIBTS-Q4 in 2011 does not appear in the FSP-ENG-MONK in 2012.

### 3.3.1.3.3 Other surveys

The coverage of the other surveys (IGFS-WIBTS-Q4 and SPPGFS (WIBTS-Q4)) are mostly outside the preferred area of the distribution of the species. Therefore information is scarce. However, in recent years the Irish Groundfish Survey (IGFS-WIBTSQ4) has shown similar patterns to that seen in the EVHOE-WIBTS-Q4 survey, suggesting a possible expansion or northerly movement of the stocks distribution. Length distributions (figure 3.3-7) and index of abundance,

Table 3.2-3, in numbers per ten square kilometres from this survey are presented.
The abundance index shows a similar drop after the peak in 2013 in the final year as that shown in the EVHOE-WIBTS-Q4. The estimated abundance in 2013 and 2014 were the highest and second highest of the time-series, respectively. The length distributions also show similar recruitment patterns in the last two years of the survey with 2013 giving the highest abundance of the time-series.

### 3.3.2 Conclusion

Survey data give indication that the biomass has shown a continuous increase since the mid 2000's as a consequence of several good incoming recruitments. There is good evidence of a strong incoming recruitment for 2008. The EVHOE-WIBTS-Q4 shows evidence of a medium level of recruitment in 2010 and in the most recent year and record strong recruitment from 2011 to 2013. Length frequency distributions from two of the available surveys, EVHOE-WIBTS-Q4 and FSP-ENG-MONK, show contradictory signals for 2009, 2011 and 2012 recruitments, but the working group considers that the trend of the EVHOE-WIBTS-Q4 is more representative due to the larger coverage of the survey.

Preliminary information on discards shows that an increasing proportion of small fish are caught and discarded (WKFLAT12) and results from this year's data available for the first time to the working group shows that around 11 percent of the catch is discarded. Due to the low levels of sampling and the uncertainties in the precision of the estimates the group recommends that the discard estimates are not used in the assessment or for advice purposes.
As discard information has been made available to the working group further years submissions will allow for a more extensive analysis of the estimates so that catch information can be presented with confidence
With the large recruitments predicted from the surveys, EVHOE-WIBTS-Q4 and IGFS-WIBTS-Q4, in 2013 and the discarding of small fish caught, measures should be taken to ensure good survival of the recent recruits such as spatial and technical measures.

The Working Group concludes that in view of the available data, continuing fishing at present level should not harm the stock.

### 3.3.3 Comments on the assessment

As for L. piscatorius, data from surveys tracking recent good recruitment give scope for growth studies and ageing validation that should be initiated as soon as possible. It is noted that this should be easier than for L. piscatorius given the length distribution observed in recent years in the EVHOE-WIBTS-Q4 survey and the last four years in the English Fisheries Science Partnership programme FSP-ENG-MONK survey.

## 4 Anglerfish (Lophius piscatorius and L. budegassa) in Divisions VIIIc and IXa

## L. piscatorius and L. budegassa

Type of assessment in 2015: Update (the assessment models and settings were approved in the benchmark WKFLAT-2012).

Software used: SS3 for L. piscatorius and ASPIC for L. budegassa.

## Data revisions this year:

For both stocks, Lophius piscatorius and L. budegassa, the following data were revised: Spanish landings and length distribution of landings for the period 2011-2013. Spanish LPUE SP-CORTR8c-PORT landings, effort, and length distribution from 2009 to 2013. Portuguese LPUE series in 2012 and 2013. Unallocated landings estimates in years 2011, 2012 and 2013.

### 4.1 General

Two species of anglerfish, Lophius piscatorius and L. budegassa, are found in ICES Divisions VIIIc and IXa. Both species are caught in mixed bottom trawl fisheries and in artisanal fisheries using mainly fixed nets.

The two species are not usually landed separately, for the majority of the commercial categories, and they are recorded together in the ports' statistics. Therefore, estimates of each species in Spanish landings from Divisions VIIIc and IXa and Portuguese landings of Division IXa are derived from their relative proportions in market samples.

The total anglerfish landings are given in Table 4.1 .1 by ICES division, country and fishing gear. Landings increasing in the early eighties and reaching maximum in 1986 (9433 t) and $1988(10021 \mathrm{t})$, and decreasing after that to the minimum in $2001(1801 \mathrm{t})$ and 2002 (1802 t). From 2002 to 2005 landings increased reaching 4541 t. In 2002-2005 period landings increased reaching 4,541 t ., this period was followed by a another one where landings gradually declined and in 2011 landings were less than half of the 2005 amount ( 2085 t ). From 2011 to 2014 landings slightly increased to 2989 t ( 2001 t of $L$. piscatorius and 988 t of L. budegassa).

The species proportion in the landings has changed since 1986. In the beginning of the time series (1980-1986) L. piscatorius represented more than $70 \%$ of the total anglerfish landings. After 1986 the proportion of L. piscatorius decreased and in 1999-2002 both species had approximately the same weight in the annual landings. Since then the $L$. piscatorius proportion increased. The mean proportion of L. piscatorius in the landings from 2005 to 2014 is $66 \%$.

ICES performs assessments for each species separately. The benchmark assessment of anglerfish in Division VIIIc and IXa was carried out in 2012, a new assessment using Stock Synthesis (SS3) for L. piscatorius was approved and new settings and data were incorporate to the ASPIC model for L. budegassa.

The ageing estimation problems, detected in a previous benchmarck (see WGHMM2007 report) continue unsolved for L. piscatorius (ICES, 2012a) and no new studies were carried out for L. budegassa. The grow pattern inferred from mark-recapture and length composition analysis (Landa et al., 2008) was used in the assessment of L. piscatorius.

### 4.2 Summary of ICES advice for 2015 and management for 2014 and 2015

## ICES advice for 2015 :

As both species of anglerfish are caught in the same fisheries and are subject to a combined TAC, the same multiplicative factor for current fishing mortality is assumed for both species. The change is driven by L. piscatorius, as it is the species in poorest condition. Following the ICES MSY approach implies fishing mortality to be increased by $14 \%$.

ICES advises the following landings for 2015 on the basis of the MSY approach:
L. piscatorius: less than 1937 t; L. budegassa: less than $1050 t$; Combined anglerfish: less than 2987 t.

Management applicable for 2014 and 2015 :
The two species are managed under a common TAC that was set at 2629 t for 2014 and 2987 t for 2015. The reported landings in 2014 were $114 \%$ of the established TAC.
There is no minimal landing size for anglerfish but an EU Council Regulation (2406/96) laying down common marketing standards for certain fishery products fixes a minimum weight of 500 g for anglerfish. In Spain this minimum weight was put into effect in 2000.

## Management considerations

Lophius piscatorius and L. budegassa are subject to a common TAC, so the joint status of these species should be taken into account when formulating management advice. Both species of anglerfish are reported together because of their similarity but are assessed separately.

It should be noted that both anglerfish are essentially caught in mixed fisheries. Hence, management measures applied to these species may have implications for other stocks and viceversa. It is necessary to take into account that a recovery plan for hake and Nephrops is taking place in the same area.

Although these stocks are assessed separately they are managed together. Due to the differences in the current status of the individual stocks, it is difficult to give common advice.

### 4.3 Anglerfish (L. piscatorius) in Divisions VIIIc and IXa

### 4.3.1 General

### 4.3.1.1 Ecosystem aspects

The ecosystem aspects of the stock are common with L. budegassa and are described in the Stock Annex.

### 4.3.1.2 Fishery description

L. piscatorius is mainly caught by Spanish and Portuguese bottom trawlers and gillnet fisheries. For some gillnet fishery, it is an important target species, while it is also a by catch of the trawl fishery targeting hake or crustaceans (see Stock Annex).

The length distribution of the landings is considerably different between both fisheries, with the gillnet landings showing higher mean lengths compared to the trawl landings. Since 2001 to 2014, the Spanish landings were on average $46 \%$ from the trawl fleet (mean lengths in 2014 of 65 cm and 59 cm in Divisions VIIIc and IXa, respectively) and $54 \%$ from the gillnet fishery (mean length of 78 cm in Division VIIIc in 2014). For the same period, Portuguese landings were on average $11 \%$ from bottom trawlers (mean length of 45 cm in 2014) and $80 \%$ from the artisanal fleet (mean length of 65 cm in 2014).

### 4.3.2 Data

### 4.3.2.1 Commercial catches and discards

Total landings by country and gear for the period 1978-2014, as estimated by the WG, are given in Table 4.3.1. A revision of Spanish landings for the period 2011-2013 were
provided to the WG. The new methodology of estimation of landings explained in Castro, 2015 (WD-03, ICES 2015a) is considered appropriate for the estimation of the stock landings of this species and new values are consistent with the time series of landings, being the new series accepted to do the assessment. Unallocated landings for this stock were available for the first time for the years 2011, 2012 and 2014 and a revision of unallocated landings for 2013 were also presented. The unallocated values are considered realistic and are taken into account for the assessment. Since 2011 there was an increasing trend in official landing with increases of $10 \%$ and $32 \%$ in 2013 and 2014 respectively. Unallocated landings represent between 7 and $20 \%$ of total landings and not a specific trend was observed.

Spanish discards estimates of L. piscatorius in weight and associated coefficient of variation (CV) are shown in the Table 4.3.2. For the available time series anglerfish discards represent less than $18 \%$ of Spanish trawl catches. The maximum value of the time series occurred in 2013 with 66 t . The Spanish gillnet fleet discards value are only available for 2013 and 2014 with quantities of 144 t and 0 t respectively. The occasional high and the zero value of discards reported for the gillnet fleet could be related with a very low sampling level. L. piscatorius discards in the Portuguese trawl fisheries are considered negligible (Fernández\&Prista, 2012; Prista et al., 2014). Based on the partial information on the Spanish and Portuguese discards the WG concluded that discards could be considered negligible.

### 4.3.2.2 Biological sampling

The procedure for sampling of this species is the same as for L. budegassa (see Stock Annex).

The sampling levels for 2014 are shown in Table 1.3. The métier sampling adopted in Spain and Portugal in 2009, following the requirement of the EU Data Collection Framework, can have an effect in the provided data. Spanish sampling levels are similar to previous years but an important reduction of Portuguese sampling levels was observed in 2009-2011, since 2012 Portugal increased the sampling effort.

## Length composition

Table 4.3.3 gives the available annual length compositions by ICES division, country and gear and adjusted length composition for total stock landings for 2014.The annual length compositions for all fleets combined for the period 1986-2014 are presented in Figure 4.3.1.

Landings in number, the mean length and mean weight in the landings between 1986 and 2014 are showed in Table 4.3.4. The lowest total number in landings (year 2001) is $4 \%$ of the maximum value (year 1988). After 2001, increases were observed up to 2006, with decreases every year since then to year 2011. Mean lengths and mean weights in the landings increased sharply between 1995 and 2000. In 2002 low values of mean lengths and mean weights were observed, around the minimum of the time series, due to the increase in smaller individuals. After that, increases were observed reaching 71 cm in 2010. In 2014 the mean weight and mean length of landings were at the highest values of the time series.

## Biological information

The growth pattern used in the assessment follows a vonBertalanffy model with fixed $\mathrm{k}=0.11$ and $\operatorname{Linf}$ estimated by the model. Length-weight relationship, maturity ogive and natural mortality used in the assessment are described in the Stock Annex.

### 4.3.2.3 Abundance indices from surveys

Spanish and Portuguese survey results for the period 1983-2014 are summarized in Table 4.3.5.

The abundance index from Spanish survey Sp-GFS-WIBTS-Q4 is shown in Figure 4.3.2. Since 2000 the highest abundance values were detected in 2001 and 2006, since this year a downward trend was observed. In 2011, the abundance and biomass indices decreased by $44 \%$ and $40 \%$, respectively, relative to 2010 values. In 2013 an increase in the index in biomass and in number was observed. Since 2013 the Sp-GFS-WIBTS-Q4 is conducted using a different vessel. The results of two inter-calibration experiments carried out between the two oceanographic vessels in 2012 and 2014 indicated that catches of white anglerfish has not been affected by the change of the vessel.

Landings, effort and LPUE data are given in Table 4.3.6 and Figure 4.3.3 for Spanish trawlers (Division VIIIc) from the ports of Santander and Avilés since 1986, for A Coruña since 1982 and for the Portuguese trawlers (Division IXa) since 1989. A Coruña fleet series (landings, effort and LPUE) were updated to incorporate years at the beginning of the series (1982-1985). Three series are presented for A Coruña fleet: A Coruña port for trips that are exclusively landed in the port, A Coruña trucks for trips that are landed in other ports and A Coruna fleet that takes into account all the trips of the fleet. For 2014 only information for A Coruña port was provided. Also a review of A Coruña port series for the period 2009-2013 is available to the WG (WD WD-04, ICES 2015a). Although A Coruña port is a potential abundance series to be used in the assessment a previous analysis of the whole time series must be done before taking it into account. The A Coruña fleet index, used in the assessment as abundance index from 1982 to 2012, is not available for 2013 and 2014.

For the Portuguese fleets, until 2011 most logbooks were filled in paper but have thereafter been progressively replaced by e-logbooks. In 2013 more than $90 \%$ of the logbooks are being completed in the electronic version. The LPUEs series were revised from 2012 onwards. To revise the series backwards further refinement of the algorithm is required.

For each fleet the proportion of the landings in the stock is also given in the table. In 2007 a data series from the artisanal fleet from the port of Cedeira in Division VIIIc was provided. This LPUE series is annually standardized to incorporate a new year data, latest available standardized series, from 1999 to 2011, is presented. Due to the reduction in the number of vessels of Cedeira fleet, this tuning series could not be considered as a representative abundance index of the stock and it is no longer recorded. Standardized effort provided for Portuguese trawl fleets (1989-2008) and their corresponding LPUEs are also given in Table 4.3.6, but not represented in Figure 4.3.3.
All fleets show a general decrease in landings during the eighties and early nineties. A slight landings increase in 1996 and 1997 can be observed in all fleets. From 2000 to 2005 Spanish fleets of A Coruña, Avilés and Cedeira show an increase in landings while the Portuguese fleets are stabilized at low levels. Since 2005 to 2009 landings from A Coruña and Cedeira fleets showed an overall decreasing trend. Proportion in total landings is higher for the Cedeira and A Coruña fleets. Landings for both Portuguese fleets increased in 2011.

Effort trends show a general decline since the mid nineties in all trawl fleets. In last five years they kept low effort values with some slight fluctuations. The artisanal fleet of Cedeira despite fluctuations along the time series shows an overall increasing trend until 2008. After this year the effort sharply declined to the minimum value of the series
in 2011. From 2007 to 2011 the effort from A Coruña fleet was reduced by $47 \%$, showing the lowest values of the series in 2011. The Portuguese Crustacean fleet shows high effort values in 2001 and 2002 that might be related to a change in the target species due to very high abundance of rose shrimp during that period.

LPUEs from all available fleets show a general decline during the eighties and early nineties followed by some increase. From 2002 to 2005 LPUEs increased for all fleets. This general LPUE trend is consistent between fleets including the artisanal fleet. In 2009 and 2010 an important increase of Cedeira LPUE was observed. Portuguese fleets shown a one-off increase in 2011.

### 4.3.3 Assessment

A new model assessment was adopted in 2012 benchmark (WKFLAT2012). The assessment approved in the WGHMM2012 was updated with 2014 data.

### 4.3.3.1 Input data

Input data used in the assessment are presented in the Stock Annex.
Due to the problems described in previous section (see Commercial catch-effort data), the A Coruña-fleet and Cedeira-fleet abundance indices for 2013 and 2014 were not included in the assessment.

### 4.3.3.2 Model

The Stock Synthesis 3 (SS3) software was selected to be used in the assessment (Methot, 2000). The description of the model including the structure, settings, and parameters assumptions are provided in the Stock Annex.

### 4.3.3.3 Assessment results

The model diagnosis is carried out means the analysis of residuals of abundance indices. Residual plots of the fits to the abundance indices are shown in Figure 4.3.4. Although some minor trends have been detected, as it happens for A Coruña indices from 1995 to 2000, it can be considered that the model follows trends of the abundance indices used in the model (A Coruña, Cedeira and the Spanish survey). Pearson residual plots are presented for the model fits to the length-composition data of the abundance indices (Figure 4.3.5). There were not detected specific patterns in any of the abundance indices. Some high positive residual are evident for A Coruña indices in the first and second quarter. Nevertheless, the model fits reasonably well.

The model estimates size-based selectivity functions for commercial fleets (Figure 4.3.6) and for population abundance indices (Figure 4.3.7). All the selection patterns were assumed constant over the time. The selection pattern for the Spanish trawl fleet is efficient for a wide range of lengths, since the smaller fishes until very large individuals. The Spanish artisanal fleet is most efficient in a narrow length range and for large fish, mainly from 75 to 90 cm . The Portuguese trawl fleet selection pattern indicates that this fishery is most efficient in the length range between 30 and 60 cm . This selection pattern shows strange selection over larger fish that could be an effect of an insufficient length sampling.

The selection patterns are equal for all quarters in A Coruña and Cedeira indices. For A Coruña index the selection pattern has a wide length range while Cedeira index shows the selectivity is directed to larger individuals. The Spanish survey index shows well defined selectivity to the smaller individuals.

### 4.3.3.4 Historic trends in biomass, fishing mortality and recruitment

Table 4.3.7 and Figure 4.3.8 provide the summary of results from the assessment model and observed landings. Maximum values of recruitment are recorded at the beginning of the time series $(1982,1986$ and 1987) with values over the 4 millions. Along the time series other high recruitment values were detected in 1989, 1994 and 2001. Since 2006 the recruitment has been below 1 million except in 2010 and 2014. Landings steadily decreased from 3.6 Kt in 2005 to 1.1 Kt in 2011, coinciding with the decrease in F, from 0.38 in 2005 to 0.17 in 2011. Respect to 2013 landings and F increased in 2014 by 32\%. From 2005 to 2012 SSB was at stable medium values around 6.5 kt , increasing to 7.8 kt in 2014.
4.3.3.5 Retrospective pattern for SSB, fishing mortality, yield and recruitment

In order to assess the consistency of the assessment from year to year, a retrospective analysis was carried out. It was conducted by removing one year (2014), two years (2014 and 2013), three years $(2014,2013,2012)$ and four years $(2014,2013,2012,2011)$ of data while using the same model configuration (Figure 4.3.9). All the retrospective analysis runs were similar in the estimates of recruitment. Although there is some uncertainty in recent recruitment estimates no consistent bias was observed. Retrospective analysis showed an underestimation of the SSB in the final years an overestimation of F. Nevertheless, there was no strong retrospective pattern and the assessment was accepted for projections.

### 4.3.4 Catch options and prognosis

### 4.3.4.1 Short-term projections

This year the projections were performed on the basis of present assessment.
For fishing mortality, the F status quo equal to 0.21, estimated as the average of fishing mortality the last three years $\mathrm{F}_{2012-2014}$ over lengths $30-130 \mathrm{~cm}$, was used for 2015 . In the case of recruitment, the geometric mean of the whole period (1980-2014) was used following one of the options indicated in the Stock Annex.

Projected landings in 2016 and SSB at the beginning of 2017 for different management options in 2016 are presented in Table 4.3.8. Under F status quo scenario in 2016 is expected a decrease in landings with respect to 2015, and an increase in SSB in 2017 with respect to 2016.

### 4.3.4.2 Yield and biomass per recruit analysis

The summary table of Yield and SSB per recruit analysis is given in Table 4.3 .9 and in Figure 4.3.10. The F that maximizes the yield per recruit, $\mathrm{F}_{\max }$, is estimated at 0.29 which is over Fsq (0.21) and which corresponds to a SPR level of $12 \%$.

The $\mathrm{F}_{0.1}$, rate of fishing mortality at which the slope of the YPR curve falls to $10 \%$ of its value at the origin, is equal to 0.19 and it is corresponding with a SPR level of $24 \%$. The fishing mortality of $\mathrm{F}_{30 \%}, 35 \%$ and $40 \%$ is estimated in $0.15,0.13$ and 0.11 respectively.

The status quo F is below Fmax and above from any of the reference points based on SSB per recruit analysis (Figure 4.3.10).

### 4.3.5 Biological Reference Points of stock biomass and yield.

Fmsy has been set to 0.19 , the value proposed by the Working Group in 2012 based on $\mathrm{F}_{0.1}$. No proposals for MSY-Btrigger has been presented. $\mathrm{F}_{0.1}$ is still estimated equal to 0.19 in the present assessment (Table 4.3.9).

| Framework | Reference <br> point | Value | Technical basis | Source |
| :--- | :--- | ---: | :--- | :--- |
|  | $\mathrm{MSY} \mathrm{Bt}_{\text {rigger }}$ | Not defined. |  | ICES, 2012b |
|  | $\mathrm{F}_{\text {MSY }}$ | 0.19 | $\mathrm{~F}_{0.1}$ |  |
| Precautionary <br> approach | $\mathrm{B}_{\text {lim }}$ | Not defined. |  |  |
|  | $\mathrm{B}_{\mathrm{pa}}$ | Not defined. |  |  |
|  | $\mathrm{F}_{\text {lim }}$ | Not defined. |  |  |
|  | $\mathrm{F}_{\mathrm{pa}}$ | Not defined. |  |  |

### 4.3.6 Comments on the assessment

The spawning stock biomass has increased since 2011. Fishing mortality in 2014 has increased by $47 \%$ related to 2011. An increase in landings occurred from 1.1 kt in 2011 to 2.0 kt in 2014.

### 4.3.6.1 Quality considerations

The available unallocated landings, for years 2011 -2014, are included into the present stock assessment, as the estimates were considered realistic information. However the importance of unallocated landings is difficult to assess and the results of the assessment could be affected by the inclusion of these data.
Uncertainty of the assessment model may have increased due to the missing data for commercial abundance indices in 2012, 2013 and 2014.

### 4.3.7 Management considerations

Management considerations are describing for both anglerfish stocks in section 4.2.

Table 4.3.6.
ANGLERFISH (L. piscatorius) - Divisions VIIIc and IXa.
Landings, fishing effort and landings per unit effort for trawl and gillnet fleets.
For landings the percentage relative to total annual stock landings is given.

### 4.4 Anglerfish (Lophius budegassa) in Divisions VIIIc and IXa

### 4.4.1 General

### 4.4.1.1 Ecosystem aspects

Biological/ecosystem aspects are common with L. piscatorius and are described in the Stock Annex.

### 4.4.2 Fishery description

L. budegassa is caught by Spanish and Portuguese bottom trawlers and gillnet fisheries. As L. piscatorius, L. budegassa is an important target species for the artisanal fleet, while it is a by catch for the trawl fleet targeting hake or crustaceans (see Stock Annex).

The length distribution of the landings is considerably different between both fisheries, with the gillnet landings showing higher mean lengths compared to the trawl landings. Since 2005, the Spanish landings were on average split 74\% from the trawl fleet (mean lengths in 2014 of 40 cm in both Divisions VIIIc and IXa), $20 \%$ from the gillnet fleet (mean length of 61 cm in 2014 in Division VIIIc) and $6 \%$ from others fleets. Portuguese landings, for the same period, were on average split, $29 \%$ from the trawl fleet (mean length of 44 cm in 2014) and $71 \%$ from the artisanal fleet (mean length of 48 cm in 2014).

### 4.4.3 Data

### 4.4.3.1 Commercial catches and discards

Total landings of L. budegassa by country and gear for the period 1978-2014, as estimated by the Working Group, are given in Table 4.4.1. See historical landings analysis in the Stock Annex. A revision of Spanish landings for the period 2011-2013 were provided to the WG. The new methodology of estimation of landings explained in Castro 2014 (WD03) is considered appropriate for the estimation of the stock landings of this species and new values are consistent with the time series of landings, being the new series accepted to do the assessment. Unallocated landings for this stock were available for the first time for the years 2011, 2012 and 2014 and a revision of unallocated landings for 2013 were also presented. The unallocated values were considered realistic and are taken into account for the assessment. From 2002 to 2007 landings increased to 1 301 t , decreasing afterwards to levels between $770-784 \mathrm{t}$ in 2009-2012. In 2012 landings reached 1139 t , but since then decreased been 988 t in 2014 .

Spanish trawl discards estimates of $L$. budegassa in weight and associated coefficient of variation (CV) are shown in Table 4.4.2. The estimated Spanish discards rate observed from 1994 to 2014, shows two picks, in 2006 (92 t) and $2010(61 \mathrm{t})$. The coefficient of variation for weight data varied from $24 \%$ to $99 \%$.

Sampling effort and percentage of occurrence of L. budegassa discards in the trawl Portuguese fisheries were presented for the 2004-2013 period (Prista et al. 2014 - WD3 WGBIE 2014). The maximum occurrence of discards in the trawl fleet targeting fish was $2 \%$ (sampling effort varies between 50 and 194 hauls per year). The maximum occurrence of discards in the trawl fleet targeting crustaceans was $8 \%$ (sampling effort varies between 28 and 111 hauls per year). Due to the low frequency of discards, it is not possible apply to anglerfish, the algorithm used in the WD for hake, at that moment discards estimates have not been calculated. The same situation was observed in 2014.

Partial information on the Spanish and Portuguese discards was available and the WG concluded that discards could be considered negligible.

### 4.4.3.2 Biological sampling

The procedure for sampling of this species is the same as for L. piscatorius (see Stock Annex).

The sampling levels for 2014 are shown in Table 1.3. The métier sampling adopted in Spain and Portugal in 2014, following the requirement of EU Data Collection Framework, can have an effect on the provided data. Spanish sampling levels are similar to previous years but an important reduction of Portuguese sampling levels was observed in 2009-2011, since 2012 Portugal increased the sampling effort.

## Length composition

Table 4.4.3 gives the annual length compositions by ICES division, country and gear and the adjusted length composition for total stock landings (excluding unallocated landings, length composition are not used in the actual assessment of L. budegassa) for 2014. The annual length compositions between 1986 and 2014 are presented in Figure 4.4.1.

In 2002 an increase of smaller individuals is apparent (around $30-35 \mathrm{~cm}$ ), that is confirmed in the 2003 length distribution. In 2006 and 2007 there was an increase in the number of smaller individuals which was confirmed by the lowest annual mean lengths ( 37 and 39 cm ) observed since 1986. From 2008 to 2013 these small fish were not observed, in 2014 a small mode was observed at smaller lengths decreasing the annual mean length. The total annual landings in numbers and the annual mean length and mean weight are in Table 4.4.4.

In 2005 the total number of landed individuals was low, being $9 \%$ of the maximum value (year 1987). In 2006 and 2007 the number of landed fish more than doubled the 2005 number. The number of landed fish decreased to a minimum in 2009. In 2010 and 2011 the number increased, but since then have been decreasing being in recent years at minimum levels. The mean weight continued at relative high levels.

### 4.4.3.3 Abundance indices from surveys

Spanish and Portuguese survey results for the period 1983-2014 are summarized in Table 4.4.5. The Portuguese survey was not performed in 2012. Considering the very small amount of caught anglerfish in the two surveys, these indices were not considered to reflect the change in the abundance of this species.

### 4.4.3.4 Commercial catch-effort data

Landings, effort and LPUE data are given in Table 4.4.6 and Figure 4.4.2 for Spanish trawlers from ports of Santander, Avilés and A Coruña (all in Division VIIIc) since 1986 and for Portuguese trawlers (Division IXa) since 1989. For each fleet the proportion related to the total landings is also given in the table.

In 2013-2014 Spain only provided information for A Coruña port series. Effort data in 2013 for this tuning fleet was calculated using the information from electronic logbooks and following different criteria than those established for previous years. In order to check the consistency of the Spanish time series a backward revision of the time series should be realized to compare the different methods of estimating and sources of information employed.

Three LPUE series were presented in the past for the A Coruña fleet: "A Coruña port" for trips that are exclusively landed in the port, "A Coruna trucks" for trips that are landed in other ports and "A Coruña fleet" that takes into account all the trips of the
fleet. The LPUE series used in the assessment (A Coruña fleet) was not update for 20132014. The new revision was carried out only for the A Coruña port series, it was not possible during the WG to analyze the potentiality of using this series for the assessment instead of the incomplete A Coruña fleet series.

For the Portuguese fleets, until 2011 most log-books were filled in paper but have thereafter been progressively replaced by e-logbooks. Since 2013 more than $90 \%$ of the logbooks are being completed in the electronic version. The LPUE series were revised from 2012 onwards. To revise the series backwards further refinement of the algorithms is required.

Excluding the Avilés and Santander fleets, from the late eighties to mid-nineties the overall trend in landings for all fleets was decreasing. A slight increase was observed from 1995 to 1998 in all fleets. The A Coruña trawler fleet showed in 2002 the most important drop in landings and in relative proportion of total landings. The lowest observed landings for both trawlers and gillnets was in 2009. From 2010 to 2012 an increase in catches were observed specially in the Portuguese fleets but decrease in recent years.

Effort trends are analysed in section 4.3.2.4.
LPUEs of Spanish Aviles and Santander fleets show high values during the second half of the 90's, while the Portuguese fleets have fluctuated. Spite the variability, from 2000 to 2005, a decreasing trend was observed for all fleets, since then a slightly increasing trend can be observed. From 2010 to 2012 an increase in catches rates were observed specially in the Portuguese fleets. In 2013 and 2014 LPUEs decrease, in the case of the Portuguese crustacean fleet the value is still high but for Portuguese groundfish fleet is around the mean.

### 4.4.4 Assessment

In WKFLAT2012 the assessment of the status of each anglerfish species was carried out separately, the white anglerfish based on SS3 model and the black anglerfish based on ASPIC (Prager, 1994; Prager, 2004). This year an update of that assessment was carried out.

### 4.4.4.1 Input data

At the WKFLAT2012 it was accepted, as the basis for advice, to run the ASPIC model with the following data series. Except for the Spanish fleet 'A Coruña', all series were updated till 2014 for this assessment:

- Spanish fleet 'A Coruña': the longest of the potential tuning series and represents the bulk of the fishery (SPCORTR8c: 1982-2012).
- Portuguese Trawler fleet directing to crustaceans (PT.crust.tr: 1989-2014).
- Portuguese Trawler fleet directing to groundfish (PT.fish.tr: 1989-2014).

The input data are presented in Table 4.4.7.

### 4.4.4.2 Model

The ASPIC (version 5.34.8) model (which implements the Schaeffer population growth model) was used for the WKFLAT 2012 assessment. Runs were performed conditioning on yield rather than on effort. The model options, the starting estimates and the minimum and maximum constraints of each parameter are indicated in the input file (Table 4.4.7).

### 4.4.4.3 Assessment results

During the WGHMM 2013, using the Stock Annex/WKFLAT2012 settings, with the inclusion of the new 2011 and 2012 data, the fit of the ASPIC model gets worse than the one performed at the benchmark. The model continued to show strong sensitivity to the starting guess settings ( $B 1 / K, M S Y, K$, seed and $q$ 's) leading to different levels of $B / B m s y$ and $F / F m s y$, nevertheless it keeps the trends in the relative biomass and fishing mortality.

It was suggested, by the ADGBBI (June 2013), that until the next benchmark that WG explores the sensitivity of $\mathrm{B} / \mathrm{Bmsy}$ and $\mathrm{F} / \mathrm{Fm}$ sy (like retrospective pattern) by keeping the $B 1 / K$ fixed (e.g. at the current value or based on some expert judgment about the state of the stock in the beginning of the time series). Following this suggestion in the WGBIE 2014 the B1/K was fixed at 0.6. Fixing B1/K the model became stable and is no more sensitivity to the starting guess settings of MSY, K and seed. This value seems reasonable but don't have a strong scientific basis, it was also the value agreed in the benchmark for the starting guess.

The correlation coefficient between input fleets is acceptable but the $r$ square between observed and fitted CPUE values are low (assessment results were uploaded in the ICES SharePoint in the Data folder). Point estimates and bias-corrected bootstrap confidence intervals for parameters are presented in Table 4.4.8, whereas Figure 4.4.3 plots observed and estimated CPUEs for each of the series used in the model. $\mathrm{B}_{2015 / \mathrm{BmSY}}$ and $\mathrm{F}_{2014} / \mathrm{F}_{\text {ms }}$ have respectively $1.93 \%$ and $-0.33 \%$ of bias and both have more than $17 \%$ relative inter-quartile ranges. Biomass in 2015 is estimated to be $98 \%$ of Bmš with $95 \%$ bias-corrected confidence interval between $74 \%$ and $122 \%$. Fishing mortality in 2014 is estimated to be 0.59 times Fmsy with $95 \%$ bias-corrected confidence interval between 0.45 and 0.83 times FmsY. MSY is estimated to be 1749 t with $95 \%$ CI from 1535 t to 1886 t.

Trends in relative biomass (Figure 4.4.4) indicate a steady decrease since the beginning of the series till 2001, since then a slight recovery was observed, been in 2015 at $98 \%$ of Bmsy. Fishing mortality remained at high levels between late eighties and late nineties, dropping after that. In 2014, fishing mortality is estimated to be below Fmš.

Comparison between the 2012 benchmark, the 2013, 2014 and the 2015 update assessments are showed in Table 4.4 .9 and Figure 4.4.5. Fixing B1/K at 0.60 don't change the trend of the previous assessments and the 2014 and 2015 results are in the middle of the previous assessments.

A retrospective analysis was done taking one each time to the accepted assessment (Figure 4.4.6). Despite some retro patron in all series the model show a good stability.

### 4.4.4.4 Sensitive analyses

The sensitive analysis was carried out to show the effect of changing $B 1 / K$ value to 0.9 , $0.8,0.7,0.6,0.5$ and 0.4 (Figure 4.4.7).

Fixing B1/K the model stabilises and the result of changing the value of the fixed B1/K don't change the F/FMSY and B/BMSY trends but just rescale the time series. In the fixed B1/K at 0.4 scenarios, MSY estimates are at or near the maximum bound, to fix this error some unrealistic value of the MSY boundaries need to be assumed.

As in 2014 the B1/K was fixed at 0.6 , this was the value agreed at the benchmark for the starting value. This value is reasonable as it is thought that the fishery started late 70's early 80 's, but there is no strong scientific basis.

### 4.4.5 Projections

Projections were performed based on the "benchmark settings" with B1/K fixed at 0.60 ASPIC estimates. The projected B/BMsY and yield are presented in Table 8.4.10, where each column corresponds to a fishing mortality scenario. Projections were performed for F status quo (assumed as the average of the last 3 years - F 2012-2014), Fmsy and with zero catches. A set of projections were performed with the necessary F reductions to obtain 2016 yield for both anglerfish species combined corresponding to the 2015 TAC ( 2987 t ) and $+/-15 \% 2015$ TAC. Projections using the same multiplicative factor of FMSY for L. piscatorius in the scenario MSY approach was also performed. The reason for this projection scenario is that L. piscatorius $\mathrm{F}_{2014}$ or $\mathrm{F}_{\text {sq }}$ are above $\mathrm{F}_{\mathrm{msy}}$ and L. budegassa $\mathrm{F}_{2014}$ are below Fmsy, so this stock will drive the management strategy.

For L. budegassa, fishing mortality equal to F status quo in 2016 is expected to keep the stock around Bmsy in 2017. The biomass is expected to increase in near future under all fishing mortality scenarios examined (Table 4.4.10).

### 4.4.6 Biological Reference Points

WKFLAT (ICES, 2012) endorsed the basis for MSY reference points previously assumed by ICES (i.e. Fmsy based on the ASPIC output and a proxy for MSY Btrigger as $50 \%$ of BMSY of the ASPIC output).

| Framework | Reference POINT | Value | Technical basis |
| :---: | :---: | :---: | :---: |
| MSY approach | MSY Btrigger | $\begin{aligned} & 50 \% \\ & \text { BMSY } \end{aligned}$ | BMSY is implicitly estimated from the surplus production model (ICES, 2012). |
|  | FMSY | Relative value. | Implicit, estimated from the surplus production model (ICES, 2012). Fishing mortality values are expressed relative to FMSY. |
| Precautionary approach | Blim | Not defined |  |
|  | Bpa | Not defined |  |
|  | Flim | Not defined |  |
|  | Fpa | Not defined |  |
| Management plan | SSBMGT | Not defined |  |
|  | FMGT | Not defined |  |

### 4.4.7 Comments on the assessment

Fixing $B 1 / K$ the model became stable and is no more sensitivity to the starting guess settings. The $B 1 / K$ was fixed at 0.6 , this was the value agreed at the benchmark for the starting value. This value is reasonable as it is thought that the fishery started late 70's early 80 's, but there is no strong scientific basis.

During the benchmark (WKFLAT 2012) the same model (SS3) applied to the white anglerfish was tested for the black anglerfish with some promising results but need to be tested more carefully before its application. SS3 is a length-based model so the length
sampling is key information for this stock. A benchmark for this stock was considered during the WG (see section 1 ).

### 4.4.8 Quality considerations

Three LPUE series were presented in the past for the A Coruña fleet: "A Coruña port" for trips that are exclusively landed in the port, "A Coruña trucks" for trips that are landed in other ports and "A Coruña fleet" that takes into account all the trips of the fleet. The LPUE series used in the assessment (A Coruña fleet) was not update for 20132014. The new revision was carried out only for the A Coruña port series, it was not possible during the WG to analyze the potentiality of using this series for the assessment instead of the incomplete A Coruña fleet series.
For the Portuguese fleets, until 2011 most log-books were filled in paper but have thereafter been progressively replaced by e-logbooks. Since 2013 more than $90 \%$ of the logbooks are being completed in the electronic version. The LPUE series were revised from 2012 onwards. To revise the series backwards further refinement of the algorithms is required.

### 4.4.9 Management considerations

Management considerations are in section 4.2.

Table 4.4.1. ANGLERFISH (L. budegassa) - Divisions VIIIc and IXa. Tonnes landed by the main fishing fleets for 1978-2014 as determined by the Working Group.

## 5 Megrim (Lepidorhombus whiffiagonis) in Divisions VIIb-k and VIIIa,b,d

Assessment type: An Update assessment has been done for this stock. This stock was benchmarked in 2012 in WKFLAT. This type of assessment is based on trends in SSB from the assessment, which includes surveys and commercial data, and a more detailed trend study on abundance of age groups from surveys and commercial fleets.
Data revisions this year: French 2013 landing revision and Spanish landings revision from 2011 to 2013 has been carried out. French discard data for 2014 are provided but not included in the assessment.

### 5.1 General

### 5.1.1 Fishery description

Megrim in the Celtic Sea, west of Ireland, and in the Bay of Biscay are caught in a mixed fishery predominantly by French followed by Spanish, UK and Irish demersal vessels. In 2014, the four countries together have reported around $96 \%$ of the total landings (Table 5.1.1.1.). Estimates of total landings (including unreported or miss-reported landings) and catches (landings+discards) as used by the Working Group up to 2014 are shown in Table 5.1.1.2. In 2012, Spanish official data for years 2011 to 2014 were included.

### 5.1.2 Summary of ICES Advice for 2015 and Management applicable for 2014 and 2015

ICES advice for 2015
ICES advises on the basis of the approach for data-limited stocks, but cannot quantify the resulting catches. The implied landings should be no more than 15180 tonnes.

## Management applicable for 2014 \& 2015

The 2014 TAC was set at 19101 t and 2015 TAC 19101 t , including a 5\% contribution of $L$. boscii in the landings for which stock there is no assessment.

The minimum landing size of megrim was reduced from 25 to 20 cm length in 2000.

### 5.2 Data

### 5.2.1 Commercial catches and discards

Stock catches for the period 1984-2014, as estimated by the WG, are given in Table 5.1.1.2.

Spanish data from 2011 to 2014 has been provided by SGP, the official national administration responsible for fishery statistics. In previous years catches have been estimated by the WG based on IEO and AZTI scientific estimations.

During Benchmark 2012, France landing data series were reviewed from 1999 onwards and final landings were provided for 2010 and 2011. Minor revisions were made for the Irish and Spanish landings and they are included in this revised data series.
Landings in 2014 are lower than in 2013 (16\%), reaching up to 13280 t.

Ireland, Spain, UK and Belgium provided discard data. France provided also discard data for 2014 that they were not provided since 1999, as data appeared to be very uncertain in relation to sampling level affecting their representatively. The group states strongly the importance of incorporating annual estimates of discards to obtain consistent data along the whole data series. Maybe also discards could explain some possible recruitment that could not be completely registered in the catch at age matrix and LPUEs.

Discard data available by country and the procedure to derive them are summarised in Table 5.2.1.1. The discards decrease in year 2000 can be partly explained by the reduction in the minimum landing size from 25 cm to 20 cm . Since 2000, an increasing trend in the discards has been observed until 2004. In 2005, the decrease in the number of small fish resulted in a large decrease of discards (Figure 5.2.1.1). In 2006 discards increased again around 23 \%, with a fluctuating trend in the following years. In 2014 discards decreased again $47 \%$ in weigth.

In the following table the discard ratio from catches in weight of the most recent years is presented.

|  | $\begin{aligned} & \text { N } \\ & \hline 0 \end{aligned}$ | N | $\begin{aligned} & \text { N } \\ & \text { O } \end{aligned}$ | $\begin{aligned} & \text { N } \\ & \text { O} \\ & \text { O} \end{aligned}$ | $\begin{aligned} & \text { N } \\ & 0 \\ & \text { in } \end{aligned}$ | $\begin{aligned} & \text { N } \\ & \text { O } \end{aligned}$ | $\begin{aligned} & \text { N } \\ & \text { O } \end{aligned}$ | No | $\begin{aligned} & \text { N } \\ & \text { O } \\ & \text { 2 } \end{aligned}$ | $\begin{aligned} & \text { N } \\ & \hline 8 \\ & \hline \end{aligned}$ | $\begin{aligned} & \text { N } \\ & 0 \\ & 0 \end{aligned}$ | $\stackrel{N}{O}$ | $\begin{aligned} & \stackrel{N}{O} \\ & \underset{N}{n} \end{aligned}$ | $\stackrel{N}{\underset{\omega}{O}}$ | $\begin{aligned} & N \\ & \underset{\sim}{\sim} \end{aligned}$ |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| Disca rd ratio (\%) | 11 | 13 | 15 | 20 | 27 | 17 | 22 | 17 | 19 | 16 | 25 | 22 | 19 | 21 | 14 |

### 5.2.2 Biological sampling

Age and Length distribution provided by countries are explained in Stock Annex- Meg 78 (Annex E).

## Age

France and Spain provided ALKs and consequently completed number and weights at age up to 2014. Ireland and UK (England and Wales) provided number at age for discards and landings up to 2014.

Age distribution for landings and discards from 1999 to 2014 are presented in Figure 5.2.2.1.

## Lengths

Table 5.2.2.1 shows the available original length composition of landings by Fishing Unit in 2014. The length compositions of the landings show an increase between 1990 and 1992 and, subsequently, a constant decrease until a rapid increase starting in 2000 (Figure 5.2.1.1) due to the change in MLS. Up to 2006, mean lengths stay relatively stable in the recent years with a decrease in length of discards. In 2013 and 2014 the mean length of landings and discards remains stable.

### 5.2.3 Surveys data

UK survey Deep Waters (UK-WCGFS-D, Depth > 180 m ) and UK Survey Shallow Waters (UK-WCGFS-S, Depth < 180 m ) indices for the period 1987-2004 and French EVHOE survey (EVHOE-WIBTS-Q4) results for the period 1997-2014 are summarised in Table 5.2.3.1.

The UK-WCGFS-D and UK-WCGFS-S show the same pattern in the indices for ages 2 and 3 since 1997; in agreement with the high values of EVHOE-WIBTS-Q4 age 1 index for the years 1998 and 2000. These high indices in the Deep component of the UK Surveys are even more remarkable in 2003 for all ages and in 2004 for the younger ages.

EVHOE-WIBTS-Q4 indices for age $1+2$ showed no evident general trend. Oscillations of high and low values are present from 2002 to 2007. In 2007 indices decreased sharply with a slight increase till 2010. From 2010 it remains quite stable with a slight increase in 2014 (Figure 5.2.3.2). In Figure 5.2.3.3 the time series of the age composition of abundances from 2007 to 2014 is presented.

An abundance index in ages was provided for Irish Groundfish Survey (IGFS-WIBTSQ4) from 2003-2014. For the last five years of the data series, the survey provides the lowest values of older ages and a sharp decrease of medium age individuals. For the younger ages, it is quite stable in the last five years.

A revised abundance index in ages was provided for the Spanish Porcupine Ground Fish Survey (SpPGFS-WIBTS-Q4) from 2001 to 2014 due to a change in the calculation methodology of the tow trawling time. In Figure 5.2.3.4 the time series of the age composition of abundances from 2007 to 2014 is presented.

When comparing Spanish, French and Irish survey biomass indices some contradictory signals are detected (Figure 5.2.3.1). The EVHOE-WIBTS-Q4 index decreased from 2001 until 2005 and since then has sharply increased until 2011. In the last years until 2014, it slightly decreased. The SpPGFS-WIBTS-Q4 Porcupine survey (SP-PGFS) shows fluctuation trends from year 2003 to 2008. Afterwards, an increasing trend is observed until 2014.

Irish Ground Fish Survey (IGFS-WIBTS-Q4) gives the highest estimates in 2005 with a decrease in trend to 2007 and increasing again till 2009 in agreement with EVHOE-WIBTS-Q4. In 2010 a sharp decreased occurred in contradiction with the French and Spanish surveys. In 2011 a slight increase occurred in agreement with Spanish survey and in 2012 and 2013 a decreased was observed again with a slight in 2014.

For a more detailed inspection of the abundances indices of different age groups, these were inspected along the whole data series for surveys (Figure 5.2.3.2). Ages groups were identified as: i) age 1 +age 2 ; ii) age 3 +age 4 +age 5 and iii) age $6+$ age 7 +age $8+$ age $9+$ age $10+$. The most abundant age group was ii) at the beginning and the end of the data series for all the surveys but it shows a decreasing trend in the last three years. Age group i) appear most abundant during years 2005 to 2008. As a consequence it is difficult to conclude on the recent abundance trends by age group.
It must be noted that the areas covered by the three surveys almost do not overlap (Figure 5.2.3.5). There is some overlap between the northern component of EVHOE-WIBTS-Q4 and the southern coverage of IGFS-WIBTS-Q4, whereas the eastern boundary of SP-PGFS essentially coincides with the western one of IGFS-WIBTS-Q4.

### 5.2.4 Commercial catch and effort data

For 2012 Benchmark, a new Irish trawler index was provided as the result of the revision carried out for the Irish Otter trawl fleet. Irish beam trawl (TBB) data is limited to TBB with mesh sizes of $80-89 \mathrm{~mm}$, larger mesh sizes are disused since 2006.

The general level of effort is described in Figure 5.2.4.1. SP-CORUTR7 and SPVIGOTR7 fleets have decreased sharply until 1993, since then it has been decreasing slightly. SP-VIGOTR7 showed a very slight increase in 2007, decreasing slightly till
2014. SP-CANTAB7 remains quite stable since 1991 and decreased slightly since 2000. In 2009, no effort has been deployed by this fleet but in 2010, some trips were recorded, for the last four years no effort was deployed. The effort of the French benthic trawlers fleet in the Celtic Sea decreased from 1991 to 1994, then increased in 1995-1996 and decreasing again in 1999. Since then, effort has been fluctuating up and down for the last 10 years. Since French logbook data were only partially available since 1999, only the LPUE data can be considered.

Commercial series of catch-at-age and effort data were available for three Spanish fleets in Subarea VII (Figure 5.2.4.2): A Coruña (SP-CORUTR7) from 1984-2014, Cantábrico (SP-CANTAB7) from 1984-2010 as no effort has been deployed by this fleet in subarea VII during the last four years and Vigo (SP-VIGOTR7) from 1984-2014. The CPUE of SP-CORUTR7 has fluctuated until 1990, when it started to decrease, with a slight increase in 2003 and a peak in CPUE in 2011 and decrease again in 2014. Over the same period, SP-VIGOTR7 has remained relatively stable until 1999, reaching in 2004 the historical maximum. In the last years it was fluctuations with a decrease in 2014. SPCANTAB7 has been fluctuating up to 1999 and then a general increasing trend is observed. No LPUE value is available for this fleet in 2009, as no effort was deployed. In 2010, LPUEs increased as a result of some trips being deployed in area VII but in 2011, but afterwards no effort was deployed.

From 1985 to 2008, LPUEs from four French trawling fleets: FR-FU04, Benthic Bay of Biscay, Gadoids Western Approaches and Nephrops Western Approaches were available. (Table 5.2.4.1.\& Figure 5.2.4.3). No data for 2009, 2010 and 2011 were provided as effort deployed by these fleet was considered, at the time of the analysis, unreliable.
The LPUE of all Irish beam trawlers fleets oscillates up and down since 2000 to 2006 following a decreasing trend. From 2007 an increase in the LPUE is observed with a slight decrease in 2014 (Figure 5.2.4.4).
Summarizing no particular LPUE changes have been observed, so no stock changes is observed.

An analysis of the abundance indices of different age groups in data series for commercial fleets was carried out (Figure 5.2.4.5). Ages groups were identified as: i) age $1+$ age 2 ; ii) age $3+$ age $4+$ age 5 and iii) age 6+age $7+$ age $8+$ age $9+$ age $10+$. For Spanish and Irish commercial fleets, the most abundant age group was ii) at the beginning and the end of the data series. Age group i) appear more abundant than older ages (ii) during years 2003 and 2004 in the Spanish fleet. French fleets appear to land mostly old individual at the beginning of the data series, while same quantities of medium age fish (group ii) and old fish (group iii) are presented till 2008. In general a marked decrease in abundance index of old fish was observed for French fleet. In 2014, a decrease is observed in Spanish and Irish fleets but the proportion of age groups catches is maintained.

Based on age groups of commercial fleets, summarizing no particular LPUE changes have been observed, so no stock changes is observed.

### 5.3 Assessment

No analytical assessment is available for this stock since 2007 consequently no forecast is either provided. This stock was Benchmarked in 2012 and a Bayesian statistical catch-at-age model was tested. Absolute values of the assessment were not accepted by the Group due to the lack of confidence on the data and deficiencies of then available data.

This year, an update assessment has been conducted using data up to year 2014, according to the settings presented in the Stock Annex. A short term projection has also been presented as a trial and results seem to be promising. However, projection script developed by Fernandez el al., (2010) should be reviewed for its use in the advice.

### 5.3.1 Data Exploratory Analysis

In summary, the stock catch-at-age matrix shows three periods: 1984-1989; 1990-1998 and 1999-2014.

The data analyzed consist of landed, discarded and catch numbers-at-age and abundance indices-at-age. Five of the available fleets were considered appropriate to inclusion in the assessment model as tuning fleets: Spanish Porcupine survey (SpPGFS_WIBTS-Q4), French Survey (EVHOE-WIBTSQ4), Vigo commercial trawl cpue series separated in two periods: 1984-1998 (VIGO84) and 1999-2010 (VIGO99), and Irish Otter trawlers lpue (IRTBB), based on their representativeness of megrim stock abundance. An exploratory data analyses was performed to examine their ability to track cohorts through time.

Several exploratory analyses were carried out on the data with the software R. The analysis of the standardized $\log$ abundance indices revealed no special trend in EVHOE-WIBTSQ4 survey (Figure 5.3.1.1). Otherwise, in SpPGFS-WIBTS-Q4 negative values for old ages from 2007 to 2011, but positive for old ages from 2012 to 2014. The analysis of the standardized log abundance indices revealed year trends for VIGO99 and the same decrease in the index of old individuals was detected by this fleet in 2008 and 2009. In 1999 and 2000, VIGO99 showed negative high values for ages 1 and 2 but in the last years positive values of ages 1-3 and bigger ages 7-9. IRTBB and SpPGFS-WIBTS-Q4 were the fleets that showed more positive values for older ages from year 2010 onwards.

The time-series of catch at age (Figure 5.3.1.2) showed very low catches of ages 1-5 from 1984 to 1989. From 2004 to 2010, the catch of older ages (>6) was remarkably low, whereas catches of ages 1 and 2 increased markedly from 2003. This could be a result of an underestimation of catches of these ages (specially age 1 ) before this year, probably, due to the sparseness of discard data in that period. For ages 6 and older, large discrepancies in the amount caught before and after 1990 are apparent, with large catches of these ages before 1990 and a decrease to almost no individuals caught at the end of the data series.

The analysis of the landings are presented since 1990 (Figure 5.3.1.3). Landings of ages 1 and 2 decreased from the beginning of the series to the last years where negative values have increased from 2009 onwards. In fact, the proportion of older ages in the landings decreased significantly from 2004 to 2009, as already discussed in relation to the catch. In 2014, ages 1 increased a lot (mainly from the Irish fleet) and older ages decreased.

The signal coming from the discard data showed that at the beginning of the data series discards of age 1 was low (Figure 5.3.1.4). Discards of this age increased along the data series, particularly from 2003 onwards. Ages 4, 5, and 6 appeared to be highly discarded in year 2004. From year 2010 to 2013, ages 1 to 3 appear to be highly discarded but in 2014 general discards decrease again.

### 5.3.2 Model

The model explored during the benchmark is an adaptation of one developed originally for the southern hake stock, published in Fernández et al. (2010). It is a statistical catch-at-age model that allows incorporating data at different levels of aggregation in different years and also allows for missing discards data by certain fleets and/or in some years. These are all relevant features in the megrim stock.
The model is described in Stock Annex of this report and also in WKFLAT 2012 report.

### 5.3.3 Results

The model results were analysed looking at three different kinds of plots: convergence plots (to analyse the convergence behaviour of the MCMC chains), diagnostic plots (to analyse the goodness of the fit) and, finally, plots of the models estimates (displaying the estimated stock status over time).
The prior settings for this run are listed in Table 5.3.3.1 and are the ones chosen in the Benchmark as the best one among the different model configurations run.
In order to be sure that the model has produced a representative sample of the posterior distribution, the MCMC chain was examined for behaviour ("convergence" properties). This was done by examining trace plots and autocorrelation plots for most parameters in the model (Figure 5.3.3.1 to Figure 5.3.3.3). The trace and autocorrelation plots showed a good behaviour in the run carried out with the model, giving support to the reliability of the outputs from the MCMC simulation conducted.

Model diagnostics plots examined were: prior-posterior plots and time series and bubble plots of the residuals. Prior-posterior distributions are shown in Figures 5.3.3.4. Posterior distributions for log-population abundance in first assessment year (1984), $\log -\mathrm{f}(\mathrm{y})$ and $\log$-catchabilities of abundance indices were much more concentrated than the priors and were often centred at different places. This indicated that the model was able to extract information from the data in order to substantially revise the prior distribution. In these cases, the model fits are mostly driven by the data, with the prior having only a small influence. The posterior distributions for log-rSPD ord log-rOTD in the first assessment year (1984) were similar to the prior distributions in most of the cases. This was especially true for log-rOTD, were data directly associated with it was not available to the model. This indicates that the available data does not contain very much information concerning these parameters and that the priors have to be chosen carefully trying to be realistic.

Time series of estimated spawning stock biomass (SSB), reference fishing mortality (Fbar), recruits and catch, landings and discards are shown in Figure 5.3.3.5. The SSB shows an overall decreasing trend from the start of the series in 1984 to 2005 with a marked increasing trend till 2014. The uncertainty in the SSB was low in the whole time series. The median recruitment fluctuated between 200000 and 300000 thousand in the whole series without any trend. As expected, uncertainty in recruitment estimates is largest at the end of the time series, as those years correspond to cohorts that are still passing through the population and additional information about them will be gained in future years. The fishing mortality showed three marked periods which coincide with the data periods, 1984-1989, 1990-1998 and 1999-2013. The lowest Fbar was observed in the first period and the highest one in the year 2005 and then it decreases until 2014 with small uncertainty. Overall, the catches showed very weak decreasing trend. The landings decreased in a higher proportion than the catches and the discards showed a decreasing trend. The uncertainty was small in all the years.

### 5.4 Retrospective pattern

Retrospective analysis was conducted for 4 years, the retrospective time series of most relevant indicators are shown in Figures 5.4.1. In terms of SSB, two groups were distinguished: one corresponding to the two shortest time series (removing the 2 and 3 final years) and a second one with the two longest time series (until 2013 and removing 1 year). The SSB estimates were very similar throughout the entire time series and there was an upward revision of SSB. The recruitment estimates towards the end of the time series showed significant revisions in the retrospective analysis, but this is something common, as recruitment in the most recent year(s) is usually not correctly estimated by assessment models. The fishing mortality was revised downwards year by year.

### 5.5 Short term forecasts

As it was mentioned in last year's report conclusions, this year trial short term projection has been developed and implemented inter-sessionally. Short-term projections have been made using Rscript developed by Fernández et al. (2010).

Results are still very preliminary as some outputs of the projection were inconsistent with the stock dynamic estimated by the assessment model. However, this script could be used as a basis to develop a projection framework in the future Inter-benchmark proposed by the working group.

### 5.6 Conclusions

The use of the Bayesian statistical catch-at-age model gives very promising results and the model is able to address the heterogeneity in the Northern Megrim data in a very satisfactory way. The model fit to the data is adequate and the WG considers that the current assessment could be fully accepted and not only as indicator of trend as in the last benchmark. Besides, the basis for short term projection was developed and projections have been carried out for the assessment but this work should be reviewed by ICES.

In the context of this review, as missing discard data from France would be provided, the WG consider important to include this data into the stock assessment model. This will need a revision of the code of the Bayesian model.

Discard data from France have been provided to the WG for year 2014, but they are not included in the assessment. They are not included because there is only one year of data. However, currently the model estimates discard data for countries that do not provide this information.
Catch, landing and discard data and survey indices do not appear to indicate the presence of important change in trends of recruitment or the overall biomass.

In the context of the current trend analysis and in view of available data, the Group concludes that the stock appears stable at the present level of fishing.Biological reference points

The calculation of possible reference points was not considered appropriate at this time due to the lack of analytical assessment.

### 5.7 Recommendations on the procedure for assessment updates and further work

It needs to be pointed out that stock data from countries should be available one month before the group starts as it was set, otherwise there is not enough time during the group to make preliminary runs to obtain the best fit of the model.

Due to this year data call, France delivered discard data for year 2014.The group appreciates delivering annual estimates of discards to explain some of the recruitment processes detected in the analysis and not completely registered in the catch at age matrix and LPUEs. Taking advantage of this first deliver, the group will try to obtain a reliable time series of French discard data and afterwards, evaluate the possibility to adapt the Bayesian model to include the new discard data.

An interbenchmark is proposed to include new discard French data into the assessment model and develop projection framework. If results and projections are appropriate a proposal to change stock category from category 3.2 to category 1 would be done.

Some recommendations are done in Annex O.

## 6 Megrims (Lepidorhombus whiffiagonis and L. boscii) in Divisions VIIIc and IXa

## Lepidorhombus whiffiagonis:

Type of assessment in 2015: Update.
Data revisions this year:
Spanish landings and Spanish length distributions of landings for the period 20112013.

Spanish efforts and LPUEs for commercial fleets in 2013.
Portuguese efforts and LPUEs for commercial fleet in 2012 and 2013.
Unallocated landings estimates in years 2011, 2012 and 2013.
Review Group issues for L.whiffiagonis: Following recommendations from RG in 2014, the following action were taken:

Year 2013 has been included in Figure 6.1.6.

## Lepidorhombus boscii:

Type of assessment in 2015: Update.

## Data revisions this year:

Spanish landings and Spanish length distributions of landings for the period 20112013.

Spanish efforts and LPUEs for commercial fleets in 2013.
Portuguese efforts and LPUEs for commercial fleet in 2012 and 2013.
Unallocated landings estimates in years 2011, 2012 and 2013.
Review Group issues for L. boscii:
Year 2013 has been included in Figure 6.2.6.

## General

See Stock annex general aspects related to megrim assessment.

## Ecosystem aspects

See Stock annex for ecosystem aspects related to megrim assessment.

## Fishery description

See Stock annex for fishery description.
Summary of ICES advice for 2015 and management for 2014 and 2015
ICES advice for 2015(as extracted from ICES Advice 2014, Book 7):
Because the two megrim species (L. whiffiagonis and L. boscii) are not separated in the landings, the advice of the two stocks is linked. Fsq is above FMSY for L. boscii and at FMSY level for L. whiffiagonis. To get fishing mortality for both stocks at or below FMSY, the F multiplier of L. boscii is applied to both stocks.

For L. boscii, following the ICES MSY approach implies fishing mortality to be reduced to 0.17 (FMSY),, resulting in landings of no more than 821 t in 2015. If discard rates do
not change from the average of the last 12 years (2002-2013), this implies catches of no more than 1036 t .This is expected to lead to an SSB of 6677 t in 2016. For L. whiffiagonis, the ICES MSY approach implies a reduction in fishing mortality to 0.11 , resulting in catches of no more than 208 t in 2015. Considering that no discard ban is in place in 2015 and if the discarding rate remains at the mean of the last three years, this would result in landings of no more 192 t . This is expected to lead to an SSB of 1343 t in 2016.

## Management applicable for 2014 and 2015:

The agreed combined TAC for megrim and four-spot megrim in ICES Divisions VIIIc and IXa was 2257 t in 2014 and 1377 t in 2015.

### 6.1 Megrim (L. whiffiagonis) in Divisions VIIIc and IXa

### 6.1.1 General

See general section for both species.

### 6.1.2 Data

### 6.1.2.1 Commercial catches and discards

Working Group estimates of landings, discards and catches for the period 1986 to 2014 are given in Table 6.1.1. Estimates of catches presently include an unallocated landing category. These estimates are considered the best information available at this time. However, given that the method of calculating them changed in 2013, the WG recommended to review the time series of unallocated landings for this stock following the same criteria. Data revised have been provided for period 2011-2013. Because this method is better to calculate the proportion between the two megrims species due to the improvement in the allocation of sampling trips, data revised have been used in the assessment. The total estimated international landings in Divisions VIIIc and IXa for 2014 was 377 t . Landings reached a peak of 977 t in 1990, followed by a steady decline to 117 t in 2002. Some increase in landings has been observed since then, but landings have again decreased annually since 2007 till 2010 were the lowest value of the entire series occurred. Since 2011, the stock is increasing again. 2011 and 2014 values represent important increments. Historical landings for both species combined are shown in Figure 6.1.1. In 2014, international landings are 1531 t, being a increase in relation to the previous year.

Discards estimates were available from "observers on board sampling programme" for Spain in the years displayed in Table 6.1.2(a). Discards in number represent between $10-45 \%$ of the total catch, with the exception of the year 2007 when discards have been very low and 2011 with discards extremely high. Following recommendations, during the Benchmark WKSOUTH in 2014, an effort was made to complete the time-series back until 1986 in years without samplings. Total discards are given in tons in Table 6.1.1 and in numbers at age in Table 6.1.2(b), these data are included in the assessment model.

### 6.1.2.2 Biological sampling

Annual length compositions of total stock landings are displayed in Figure 6.1.2 for the period 1986-2014 and in Table 6.1.3. (a)Unallocated value is raised to total length distribution. ,. The bulk of sampled specimens corresponds to fish of $21-36 \mathrm{~cm}$.

Sampling levels for both species are given in Table 1.3.

Mean lengths and mean weights in landings since 1990 are shown in Table 6.1.3(b). The mean length and mean weight values in 2013 are the highest in the historic series.

Age compositions of catches are presented in Table 6.1.4 and weights-at-age of catches in Table 6.1.5, from 1986 to 2014. These values were also used as the weights-at-age in the stock.

More biological information and the parameters used in the length-weight relationship, natural mortality and maturity ogive are shown in the stock annex.

### 6.1.2.3 Abundance indices from surveys

Two Portuguese (PtGFS-WIBTS-Q4, also called "October" survey, and PT-CTS (UWTV (FU 28-29)), also called "Crustacean" survey) and one Spanish (SpGFS-WIBTS-Q4) survey indices are summarised in Table 6.1.6. In 2012, Portuguese surveys were not conducted due to budgetary constraints of national scope turned unfeasible to repair the R/V.

As noted in the Stock Annex, indices from these Portuguese surveys are not considered representative of megrim abundance, due to the very low catch rates.

The Spanish survey (SpGFS-WIBTS-Q4) covers the distribution area and depth strata of this species in Spanish waters (covering both VIIIc and IXa). Total biomass and abundance indices from this survey were higher during the period 1988-1990, subsequently declining to lower mean levels, which are common through the rest of the time series. There has been an overall declining trend in the abundance index after year 2000, with the values for 2008 and 2009 being the two lowest in the entire series. Since then, there is a general increasing trend. (Figure 6.1.3(a), bottom right panel). In 2013 the survey was carried out in a new vessel and with new fishing doors. This year the abundance indices are high for flatfish and benthic species. Although there was an inter-calibration exercise between both vessels, the results were not consistent with the results of the inter-calibration, therefore the working group decided not to include the abundance index value for that year in the assessment model. In 2014 the gear used was similar to the gear used in the survey before 2013. A new inter-calibration exercise was conducted in 2014. The index for 2014 was found consistent with the index before 2013 and the working group decided to use it. However for 2013 the index is still inconsistent with the time series and the group decided not to include it.

The Spanish survey recruitment indices for ages 0 and 1 indicate an extremely weak year class in 1993, followed by better recruitments, except for relatively low values for the 1997 and 1998 year classes. The 1999 year class appears to be relatively strong compared to those from previous years, but the 2000 to 2005 year classes again appear to be low. The survey indicates extremely low values at age 0 for years 2006-2008, with 2006 and 2008 being equal worst with 1993 in the historic series. In 2009, the age 0 index is the highest after 2001, whereas the age 1 index is the second lowest in the series. In 2010, there is a very important increase in age 1, being the highest value since 1996. In 2014 ages 0 is in a medium level in relation to historical values and age 1 is a low level.

Catch numbers-at-age per unit effort and effort values for the Spanish survey are given in Table 6.1.7. In addition, Figure 6.1.3(b) displays a bubble plot of $\log$ (survey indices-at-age), with the values for each age standardised by subtracting the mean and dividing by the standard deviation over the years. The size of the bubbles is related to the magnitude of the standardised value, with white and black bubbles corresponding to positive and negative values, respectively. The figure indicates that the survey is quite
good at tracking cohorts through time and highlights the weakness of the last few cohorts. The big age 1 index in 2010 is also detected in this figure and can be followed through the following years..

### 6.1.2.4 Commercial catch-effort data

The commercial LPUE and effort data of the Portuguese trawlers fishing in Division IXa covers the period 1988-2014 (Table 6.1.8 and Figure 6.1.3(a)).

It is known that the Northern Spanish coastal bottom otter trawl fleet is a fleet deploying a variety of fishing strategies with different target species. In fact, these fishing strategies are identified under the current DCF sampling programme, so that they can be then re-aggregated under two DFC métiers: bottom otter trawl targeting demersal species (OB_DEF_>=55_0_0) and OTB targeting pelagic stocks accompanied by some demersal species (OTB_MPD_>55_0_0). Therefore, the LPUE of these métiers was recovered backwards (until 1986) and two new time-series of bottom otter trawl targeting demersal species, one per port (A Coruña and Avilés), were provided to the Benchmark WKSOUTH in 2014. These new tuning fleets (SP-LCGOTBDEF and SP-AVSOTBDEF) were accepted to tune the assessment model instead of the old ones A Coruña trawl (SP-CORUTR8c) and Avilés trawl (SP-AVILESTR). The LPUEs and effort values are given in Table 6.1.8 and Figure 6.1.3(a).

## Commercial fleets used in the assessment to tune the model

Before 2003, A Coruña (SP-LCGOTBDEF) effort was generally stable. After that year, the trend was similar but in lower values. The 2011 effort value is the lowest in the series. In 2014, effort is the highest value. The LPUE shows relatively high stable values for 1986 - 2002. Since 2003 LPUE shows lower values, is increasing since 2010 till 2012 and the last two years is decreasing.
Avilés (SP-AVSOTBDEF) effort does not present any trend throughout the whole period. The highest value occurred in 1998 and the lowest in 2001. LPUE shows a decreasing from 1986 to 2003. Since then, it has had a further upward and downward fluctuation, with a peak in 2011. Landed numbers-at-age per unit effort and effort data for these fleets are given in Table 6.1.7.

Figure 6.1.3(c) displays bubble plots of standardised log (landed numbers-at-age per unit effort) values for these commercial fleets, with the standardisation performed by subtracting the mean and dividing by the standard deviation over the years. The panel corresponding to A Coruña trawl fleet clearly indicates below average values since about year 2003, in 2011 and 2012 values are above average but in the last two years the values fell again.

## Commercial fleets not used in the assessment to tune the model

Portuguese effort values are quite variable, except in 2001 and 2002 when they are significantly lower (Table 6.1.8 and Figure 6.1.3(a)). For the Portuguese fleets, until 2011 most log-books were filled in paper but have thereafter been progressively replaced by e-logbooks. In 2013 more than $90 \%$ of the log-books are being completed in the electronic version. The LPUE series were revised from 2012 onwards. To revise the series backwards further refinement of the algorithms is required. The LPUE shows a steep decrease between 1990 and 1992, and has since remained at low levels, with the exception of a peak in 1997-1998. LPUE for 2014 represent an increase in relation to the previous year.

### 6.1.3 Assessment

An update assessment was conducted, according to the Stock Annex specifications. Assessment years are 1986-2014 and ages 1-7+.

### 6.1.3.1 Input data

It follows the Stock Annex, incorporating discards and landed numbers-at-age resulting in catch numbers-at-age as input data from 1986 to 2014 and the 2014 indices from A Coruña (SP-LCGOTBDEF) tuning fleet and Avilés tuning fleet (SP-AVSOTBDEF) and Spanish survey (SpGFS-WIBTS-Q4).

### 6.1.3.2 Model

## Data screening

Figure 6.1.4(a) shows catch proportion at age where higher proportions can be observed for ages 1 and 2 till 2000 due to the high discards at these ages in this period. The top panel of Figure 6.1.4(b) shows landings proportions at age, indicating that the bulk of the landings consisted of ages 1 and 2 before 1994, shifting after that mostly to ages 2 to 4 . The bottom panel of the same figure displays standardised (subtracting the mean and dividing by the standard deviation over the years) proportions at age, indicating the same change around the mid 1990's, with proportions at age decreasing for ages 1 and 2 and increasing for the older ages. Some weak and strong cohorts can be noticed in this figure, particularly around the mid 1990's. The 2010 year shows an increase in landings of older ages, especially ages 4 to $7+$. The high abundance of age 0 in the Spanish survey in 2009 can be tracked following years. Figure 6.1.4(a) shows discards proportion at age, being more abundant for age 1 from 2000 onwards. Before this year, discarding was higher in age 2. Visual inspection of Figures 6.1.3(b) and 6.1.3(c) indicates that all tuning series are good up to age 5 in relation to their internal consistency. Age 6 is harder to track along cohorts, particularly for the Spanish survey and the A Coruña tuning fleet.

## Final run

XSA model was selected for use in this assessment. Model description and settings are those detailed in the Stock Annex.

The retrospective analysis shows a small but consistent pattern of overestimation of SSB and underestimation of F and recruitment in recent years (Figure 6.1.5).

### 6.1.3.3 Assessment results

Diagnostics from the XSA run are presented in Table 6.1.9 and log catchability residuals plotted in Figure 6.1.6. For all tuning fleets the magnitude of the residuals is larger for older ages. Residuals in A Coruña tuning fleet in the last years present mainly positive values. Until 1997 many of the survey residuals were negative, whereas many are positive since 1999. Since 2008, there appears to be a change towards negative survey residuals again. Several year effects are apparent in all tuning series. As has been the case in the last few years the model shows that it hasn't converged, however the differences which activate this criteria was so small ( 0.00085 difference) and close to zero that we have confidence that the assessment has converged. The results presented correspond to a run of 160 iterations, as increasing the number of iterations led to larger total absolute residuals value between iterations.

Fishing mortality and population numbers at age from the final XSA run are given in Tables 6.1.10 and 6.1.11, respectively, and summary results presented in Table 6.1.12 and Figure 6.1.7(a).

Fishing mortality presents an increasing trend since 2011, which may be explained by the increase in landings in that years. The SSB values in 2007-2010 are the lowest in the series. Since 2011 values are significantly higher and more or less stable. After a very high recruitment (at age 1) value in the series in 2010 and the followings decreases and increase in 2013, the last year the recruitment value shows a decrease.

Bubble plots of standardised (by subtracting the mean and dividing by the standard deviation over the years) estimated F-at-age and relative F-at-age (F-at-age divided by Fbar) are presented in Figure 6.1.7(b). The top panel of the figure indicates that fishing mortality has been lower for all ages since about year 2000. The reduction occurred earlier for ages 1 and 2, at around 1994. In terms of the relative exploitation pattern-atage (bottom panel of the figure), the most obvious changes are the reduction for ages 1 and 2 around 1994 and the increase for age 3 soon after that. This might be related to discarding practices. There is no clear pattern over time in the age 4 selection, whereas for ages 5 and older there seems to have been an increase during the mid to late 1990's but they have since come back down to lower values. Since 2010, there appears to have been an increase of the relative exploitation towards older ages, with high values above the average for ages 5 to $7+$.

### 6.1.3.4 Year class strength and recruitment estimations

The 2011 year class is estimated to have 3.1 million fish at 1 year of age, based on the Spanish survey (SpGFS-WITBS-Q4) (55\% of weight), two commercial fleets SPLCGOTBDEF ( $22 \%$ of weight) and SP-AVSOTBDEF ( $17 \%$ of weight) and F shrinkage (6\%).

The 2012 year class is estimated to have 5.1 million individuals at 1 year of age based on the information from the Spanish survey (SpGFS-WIBTS-Q4) ( $54 \%$ of weight), Pshrinkage ( $41 \%$ of the weight) and F shrinkage (5\%).

The 2013 year class is estimated to have 3.9 million fish at 1 year of age, based on the information from the Spanish survey (SpGFS-WIBTS-Q4) (64\% of weight), P-shrinkage ( $31 \%$ of the weight) and F shrinkage (5\%).

The working group considered that the XSA last year recruitment is poorly estimated. In accordance with the stock annex specifications, GM recruitment is computed over years 1998-2012. Working Group estimates of year-class strength used for prediction can be summarised as follows:

Recruitment at age 1 :

| Year class | Thousands | Basis | Surveys | Commercial | Shrinkage |
| :--- | :--- | :--- | :--- | :--- | :--- |
| 2011 | 3130 | XSA | $55 \%$ | $29 \%$ | $6 \%$ |
| 2012 | 5086 | XSA | $54 \%$ | $0 \%$ | $46 \%$ |
| 2013 | 3250 | GM (98-12) |  |  |  |
| 2014 | 3250 | GM (98-12) |  |  |  |

### 6.1.3.5 Historic trends in biomass, fishing mortality and recruitment

From Table 6.1.12 and Figure 6.1.7, we see that SSB decreased from 2449 t in 1990 to 1017 t in 1995. From 1996 to 2003, it remained relatively stable at low levels with an average value of around 1200 t . Starting from 2004, SSB is estimated to have been even lower. The values for 2004-2010 are the lowest in the series, with SSB in 2009 and in $2010(707 \mathrm{t})$ corresponding to the lowest values. Since 2011, SSB values are increasing, being 1311 t , the 2014 value, the highest of the last years.

After a decline from 2006 (0.39) to 2010 (0.08), the fishing mortality follows an increasing trend up to a value of 0.36 in 2014.

Recruitment (at age 1) varies substantially throughout the time series, but shows a general decline from the high levels seen until the 1992 year class. Since 1998 recruitment has been continuously at low levels (recruitment in 2009 is estimated to be the lowest value of the series). In 2010 a good recruitment occurred, with a value more similar to those estimated for the previous decade. However, in 2011 and 2012, values of recruitments decreased again. 2013 showed a small increase followed by a decrease in the last year.

### 6.1.3.6 Catch Options and prognosis

Stock projections were calculated according to the settings specified in the Stock Annex.

### 6.1.3.7 Short-term projections

Short-term projections have been made using MFDP.
The input data for deterministic short-term predictions are shown in Table 6.1.13. The exploitation pattern used was the scaled F-at-age computed for each of the last five years and then the average of these scaled 2010-2014 years was weighted to the final year. This selection pattern was split into selection-at-age of landings and discards (corresponding to $\mathrm{Fbar}=0.25$ for landings and Fbar= 0.02 for discards, being 0.27 for catches).

According with stock annex, GM recruitment is computed over years 1998-2012. Age 2 for 2015 is replaced by GM98-12 reduced by total estimated mortality.

Management options for catch prediction are in Table 6.1.14. Figure 6.1 .8 shows the short-term forecast summary. The detailed output by age group assuming status quo F for 2015-2017 is given in Table 6.1.15 for landings and discards.

Under status quo F, landings in 2015 and 2016 are predicted to be 309 t and 281 t respectively, and discards 25 t in both years. SSB would decrease from the 1104 t estimated for 2015 to 1002 t in 2016 and to 911 t in 2017.

The contributions of recent year classes to the predicted landings in 2016 and SSB in 2017, assuming GM98-12 recruitment, are presented in Table 6.1.16. The assumed GM9912 age 1 recruitment for the 2014 and 2015 year classes contributes $15 \%$ to landings in 2016 and $41 \%$ to the predicted SSB at the beginning of 2016. Megrim starts to contribute strongly to SSB at 2 years of age (see maturity ogive in Table 6.1.13).

### 6.1.3.8 Yield and biomass per recruit analysis

The results of the yield- and SSB-per-recruit analyses are in Table 6.1.17 (see also left panel of Figure 6.1.8, which plots yield-per-recruit and SSB-per-recruit versus Fbar). Assuming status quo exploitation Fbar $=0.25$ for landings and Fbar=0.02 for discards
and GM98-12 for recruitment, the equilibrium yield would be 201 t of landings and 24 t of discards with an SSB of 780 t .

### 6.1.4 Biological reference points

The stock-recruitment time series is plotted in Figure 6.1.9.All recruitment values since 1998 have been low, until 2010, with a very high recruitment value, followed by not so higher ones.

See Stock Annex for information about Biological reference points.
The BRP are:

|  | Type | Value | Technical basis |
| :--- | :--- | :--- | :--- |
| MSY | MSY Btrigger | 910 t | default option; 1.4 Blim |
| Approach | FMSY | 0.17 | 650 t |
|  | Blim | Fmax as FMSY proxy <br> assessment |  |
| Precautionary | Bpa | 910 t | default option; 1.4 Blim |
| Approach | Flim |  |  |
|  | Fpa |  |  |

### 6.1.5 Comments on the assessment

The behaviour of commercial fleets with regards to landings of age 1 individuals appears to have changed in time. Hence, data from commercial fleets used for tuning is only taken for ages 3 and older. However, the Spanish survey (SpGFS-WIBTS-Q4) provides good information on age 1 abundance.

Comparison of this assessment with the one performed last year shows that there are minor differences in F and SSB in the last years, maybe due to the increase in landings in 2014 (Figure 6.1.10)

Megrim starts to contribute strongly to SSB at 2 years of age. Around $40 \%$ of the predicted SSB in 2016 relies on year classes for which recruitment has been assumed to be GM98-12.

### 6.1.6 Management considerations.

It should be taken into account that megrim, L. whiffiagonis, is caught in mixed fisheries. There is a common TAC for both species of megrim (L. whiffiagonis and L. boscii), so the joint status of the two species should be taken into consideration when formulating management advice. Megrims are by-catch in mixed fisheries generally directed to white fish. Therefore, fishing mortality of megrims could be influenced by restrictions imposed on demersal mixed fisheries, aimed at preserving and rebuilding the overexploited stocks of southern hake and Nephrops.

This is a small stock (average stock SSB since 1986 is 1300 t ). Managing according to a very low F for megrim could cause serious difficulties for the exploitation of other stocks in the mixed fishery (choke species effect). Both Iberian megrim stocks are assessed separately but managed together, situation that may produce inconsistencies when these stocks are considered in a mixed fisheries approach. In fact, this effect was observed in the results of the last mixed fisheries analysis developed for Iberian stocks by the WGMIXFISH_METH (ICES, 2013).Of course, any F to be applied for the management of megrim must be in conformity with the precautionary approach.

Working group considers that this stock could be just "the tail" of the much larger stock of megrim in ICES Subarea VII and Divisions VIIIabd. Genetic studies on 16S rDNA gene from several samples from the Atlantic area show that there is not a clear differentiation between the northern and southern stocks considered by ICES (GarcíaVázquez et al., 2006). This could also explain why a prolonged decrease in F was not reflected in stock increases. One suggested option is to reconsider the stock limits and the inclusion in the Northern megrim stock.

Table. 6.1.1 Megrim (L. whiffiagonis) in Divisions VIIIc, IXa. Landings, discards and catch ( t ).

| Year | Spain landings |  |  | $\begin{array}{\|c\|} \hline \text { Portugal landings } \\ \hline \text { IXa } \\ \hline \end{array}$ | Unallocated | Total landings | Discards | Total catch |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
|  | VIIIC | IXa*** | Total |  |  |  |  |  |
| 1986 | 508 | 98 | 606 | 53 |  | 659 | 46 | 705 |
| 1987 | 404 | 46 | 450 | 47 |  | 497 | 40 | 537 |
| 1988 | 657 | 59 | 716 | 101 |  | 817 | 42 | 859 |
| 1989 | 533 | 45 | 578 | 136 |  | 714 | 47 | 761 |
| 1990 | 841 | 25 | 866 | 111 |  | 977 | 45 | 1022 |
| 1991 | 494 | 16 | 510 | 104 |  | 614 | 41 | 655 |

Extended Survivors Analysis
Megrim (L. whiffiagonis.) in Divisions VIIIc and IXa

CPUE data from file fleetw.txt

Catch data for 29 years. 1986 to 2014 . Ages 1 to 7 .

| Fleet | First Last |  |  |  |  |  |
| :--- | :---: | ---: | :---: | ---: | :---: | ---: | ---: | ---: |
|  | yearyear | First <br> age | Last <br> age | Alpha |  | Beta |

Time series weights

Tapered time weighting not applied

Catchability analysis :

Catchability dependent on stock size for ages < 3

Regression type $=\mathrm{C}$
Minimum of 5 points used for regression
Survivor estimates shrunk to the population mean for ages < 3

Catchability independent of age for ages $>=5$

Terminal population estimation :

Survivor estimates shrunk towards the mean F
of the final 5 years or the 3 oldest ages.
S.E. of the mean to which the estimates are shrunk $=1.500$

Minimum standard error for population
estimates derived from each fleet $=.200$

Prior weighting not applied
Tuning had not converged after 160 iterations
Total absolute residual between iterations
159 and $160=.00085$

Final year F values
Age
Iteration **

### 6.2 Four-spot megrim (Lepidorhombus boscii)

### 6.2.1 General

See general section for both species.

### 6.2.2 Data

### 6.2.2.1 Commercial catches and discards

The WG estimates of four-spot megrim international landings, discards and catches for the period 1986 to 2013 are given in Table 6.2.1. Estimates of catches presently include an unallocated landing category. These estimates are considered the best information available at this time. However, given that the method of calculating them changed in 2013, the WG recommended to review the time series of unallocated landings for this stock following the same criteria. Data revised have been provided for period 20112013. Because this method is better to calculate the proportion between the two megrims species due to the improvement in the allocation of sampling trips, data revised have been used in the assessment. Landings reached a peak of 2629 t in 1989 and have generally declined since then to their lowest value of 720 t in 2002. There has been some increase again in the last few years. Landings in 2010 are 1297 t , the highest value after 1995. After a similar value in 2011, landings in 2013 are 931 t , a significant drop. In 2014, landings increase to 1154 t .

Discards estimates were available from "observers on board sampling programme" for Spain in the years displayed in Table 6.2.2(a). Discard / Total Catch ratio and CV are also presented, where discards in number represent between 39-67\% of the total catch. Following the ICES recommendations in the advice sheet and using the same methodology described for L. whiffiagonis in section 6.1.2.1, discards missing data were also estimated for L. boscii in the Benchmark WKSOUTH in 2014. Spanish discards in num-bers-at-age are shown in Table 6.2.2(b), indicating that the bulk of discards (in numbers) is for ages 1 to 3 Total discards are given in tons in Table 6.2.1

### 6.2.2.2 Biological sampling

Annual length compositions of total stock landings are given in Figure 6.2.1 and Table 6.2.3(a) for the period 1986-2014. Unallocated value is raised to total length distribution.

Mean length and weights in landings since 1990 are shown in the Table 6.2.3(b).
Age compositions of catches are presented in Table 6.2.4 Weights-at-age of catches (given in Table 6.2.5) were also used as weights-at-age in the stock. There is some variability in the weights-at-age through the historical time series.

For more information about biological data see Stock Annex.

### 6.2.2.3 Abundance indices from surveys

Portuguese and Spanish survey indices are summarised in Table 6.2.6.
Two Portuguese surveys, named "Crustacean"' (PT-CTS (UWTV(FU28-29))) and "October"' (PtGFS-WIBTS-Q4), provide indices for 2014. The October survey was conducted with a different vessel and gear in 2003 and 2004. Excluding these two years, the biomass indices from this survey in 2007 and 2011 were the highest observed since 1994, whereas the value in 2010 is the second lowest in the series. In 2011, both the biomass and abundance indices from the Crustacean survey are the highest in the time
series. In 2012, Portuguese Survey was not carried out due to budgetary constraints of national scope turned unfeasible to repair the R/V. In 2014 shows a low value of abundance.

Total biomass, abundance and recruitment indices from the Spanish Groundfish Survey (SpGFS-WIBTS-Q4) are also presented in Table 6.2.6. Total biomass indices from this survey generally remained stable after a maximum level in 1988 till 2003, when a very low value was obtained (as done in previous years, the 2003 index has been excluded from the assessment, as it was felt to be too much in contradiction with the rest of the time series). Since then, this was followed by the period of the higher values till present days, with the only exception of 2008. In 2013, the biomass and the abundance indices were the highest of the series. For the same raison that for L. whiffiagonis, survey carried out in a new vessel and with new fishing doors, the abundance values of 2013 is not included in the assessment models.

The recruitment index for age 0 in 2005 was very high and also in 2009 and 2014. After two years in low levels, in 2012 the recruitment index shows a small increase, being lower in 2013. The high index in 2009 applies to all ages and not just the recruitment (see Table 6.2.7, which gives abundance indices by age, and Figure 6.2.2, which is a bubble plot of $\log$ (abundance index at age) standardised by subtracting the mean and dividing by the standard deviation over the years). It seems to be a "year" effect in 2013 values, probably due to the new vessel. In 2014, only age 1 index is below average, whereas indices for the other ages are very high. From Figure 6.2 .2 , the survey appears to have been quite good at tracking cohorts, in the last ten years, good cohorts of 2005 and 2009 can be followed, specially the second one.

### 6.2.2.4 Commercial catch-effort data

Two new commercial tuning indices were provided also for this stock as in the case of L. whiffiagonis. The LPUEs of the métiers of bottom otter trawl targeting demersal species, previously describe in section 6.1.2.4, one per port (A Coruña and Avilés), were made available for the benchmark WKSOUTH in 2014. From these new tuning fleets, SP-LCGOTBDEF and SP-AVSOTBDEF, only the first one was accepted to tune the assessment model. The LPUEs and effort values and landed numbers-at-age are given in Table 6.2.7 and Figure 6.2.3(a).

These fleets operate in different areas, each covering only a small part of the distribution of the stock, which may partly explain differences between patterns from these fleets and those from the Spanish survey in some years. Furthermore, commercial catches are mostly composed of ages 3 and 4, while the Spanish survey catches mostly fish of ages 1 and 2.
Table 6.2.8 displays landings (in tonnes), fishing effort and LPUE for the two Spanish trawl fleets just mentioned for the period 1988-2014 and for the Portuguese trawl fleet fishing in Division IXa for the period 1988-2014 (see also Figure 6.2.3). After very high value in 2010, the LPUE of Coruña (SP-LCGOTBDEF) shows in 2014 a similar value to 2012, decreasing in relation to last year. A decrease is observed in the LPUE from Avilés (SP-AVSOTBDEF) in 2014. For the Portuguese fleets, until 2011 most log-books were filled in paper but have thereafter been progressively replaced by e-logbooks. In 2013 more than $90 \%$ of the log-books are being completed in the electronic version. The LPUE series were revised from 2012 onwards. To revise the series backwards further refinement of the algorithms is required.

## Commercial fleets used in the assessment to tune the model

Because of the trend in the residuals, A Coruña fleet (SP-LCGOTBDEF) was split in two (SP-LCGOTBDEF -1 and SP-LCGOTBDEF-2) for tuning, considering values until 1999 and from 2000 to 2014, as indicated in the Stock Annex. In Figure 6.2.3(b), the bubble plots of $\log$ (abundance index at age) standardised by subtracting the mean and dividing by the standard deviation over the years) of these two fleets are presented. Some cohorts can be followed in the time series. The effort of this fleet had been generally stable till year 2009, when effort is declining to its lowest value in the series, reached in 2011. After this year, the effort is increasing, being the 2014 value the highest of the time series.

## Commercial fleets not used in the assessment to tune the model

The effort of the Avilés fleet (SP-AVSOTBDEF) present two periods, the first one with a mean value of 3.2 and the second with 2.2 (days $/ 1000) \times(\mathrm{HP} / 100)$. The value in 2013 is the second lowest in the series, increasing in 2014.

The effort of the Portuguese trawl fleet appears to fluctuate within stable bounds, with the lowest values corresponding to 1999 and 2000. It shows a slightly declining trend through the 1990s until these two lowest years and a slightly increasing one since then.

The LPUE series from the Avilés trawl fleet (SP-AVILESTR) shows a generally upwards trend during all the series. The value in 2013 is a big increase. The LPUE of the Portuguese trawl fleet has generally declined since 1992, with an increase in the last year till 2010, when the values started a decreasing trend. The value in 2014 shows a small increase.

### 6.2.3 Assessment

An update assessment was conducted, according to the Stock Annex specifications. Assessment years are 1986-2014 and ages 0-7+.

### 6.2.4 Model

## Data screening

Figures 6.2.4(a), (b) and (c) are bubble plots representing catch, landings and discards proportions at age. These plots clearly indicate that the bulk of the landings generally corresponds to ages 2 to 4 and the discards at ages 1-2. The bottom panel of Figures 6.2.4(a), (b) and (c) also present bubble plots corresponding to standardized catch, landings and discards proportions at age, showing that the one corresponding to landings is the best to follow cohorts.

Very weak cohorts corresponding to year classes of 1993 and 1998 can be clearly identified from the standardized landing proportions at age matrix and good cohorts corresponding to year classes of 1991, 1992, 1995 and 2005 can also be tracked.

## Final XSA run

Settings for the assessment are those detailed in the Stock Annex.
The retrospective analysis shows no particular worrying features (Figure 6.2.5). The model has a tendency to underestimate F and an overestimate SSB in the last years.

### 6.2.4.1 Assessment results

Diagnostics from the XSA final run are presented in Table 6.2.9 and log catchability residuals plotted in Figure 6.2.6. Diagnostics and residuals are similar to those found in the previous assessment. Many of the survey residuals are negative until the mid 1990's. After that, positive survey residuals are more abundant in this period.

Table 6.2.10 presents the fishing mortality-at-age estimates. Fbar $\left(=\mathrm{F}_{2-4}\right)$ is estimated to be 0.39 in 2014.

Population numbers-at-age estimates are presented in Table 6.2.11.

### 6.2.4.2 Year class strength and recruitment estimations

The 2012 year class estimate is 78 million individuals, obtained by averaging estimates coming from the Spanish survey tuning data ( $92 \%$ of weight)and F-shrinkage ( $8 \%$ weight).

The 2013 year class estimate is 42 million individuals, estimated from the Spanish survey ( $93 \%$ of weight) and F-shrinkage ( $7 \%$ weight).

The 2014 year class estimate is 121 million individuals, obtained a value from the Spanish survey ( $100 \%$ weight).

The working group considered that the XSA last year recruitment is poorly estimated. Following the procedure stated in the Stock Annex, the geometric mean of estimated recruitment over the years 1990-2012 has been used for computation of 2014 and subsequent year classes, for prediction purposes. Working Group estimates of year-class strength used for prediction are:

Recruitment at age 0 :

| Year class | Thousand | Basis | Survey | Commercial | Shrinkage |
| :--- | :--- | :--- | :--- | :--- | :--- |
| 2012 | 77937 | XSA | $92 \%$ | - | $8 \%$ |
| 2013 | 41612 | XSA | $93 \%$ | - | $7 \%$ |
| 2014 | 43560 | GM90-12 |  | - |  |
| 2015 | 43560 | GM90-12 |  |  |  |

### 6.2.4.3 Historic trends in biomass, fishing mortality, and recruitment

Estimated fishing mortality and population numbers-at-age from the XSA run are given in Tables 6.2.10 and 6.2.11. Further results, including SSB estimates, are summarised in Table 6.2.12 and Figure 6.2.7(a).

SSB decreased gradually from 6790 t in 1989 to 3316 t in 2001, the lowest value in the series, and has since increased. In 2014 the SSB is estimated at $6725 t$, one of the highest.

Recruitment has fluctuated around 45 million fish during all the series. Very weak year classes are found in 1993 and 1998. The second highest value occurred in 2009, while 2014 value is the highest in the series, with 121 million fish.

Estimates of fishing mortality values show two different periods: an initial one with higher values from 1989 to 1996 and, following a decrease in 1997, a second period stabilised at a lower level, with small ups and downs. From 2007, the F has been decreasing till the last two years, especially in the last, when a significant increase has occurred with a value of 0.39.

There seems to be interannual variability in the relative fishing exploitation pattern at age (F over Fbar, see Figure 6.2.7(b), bottom panel), with alternating periods of time with higher and lower relative exploitation pattern on the older ages.

### 6.2.5 Catch options and prognosis

Stock projections were calculated according to the settings specified in the Stock Annex.

### 6.2.5.1 Short-term projections

Short-term projections have been made using MFDP software. The input data for deterministic short-term projections are given in Table 6.2.13. The exploitation pattern used was the scaled F-at-age computed for each of the last five years and then the average of these scaled 2010-2014 years was weighted to the final year. This selection pattern was split into selection-at-age of landings and discards (corresponding to Fbar $=0.19$ for landings and Fbar=0.11 for discards, being 0.30 for catches). The recruitment in 2014 (age 0) has been replaced by GM, age 1 in 2015 has been recalculated from GM reduced by total estimated mortality.

Table 6.2.14 gives the management options for 2016, and their consequences in terms of projected landings and stock biomass. Figure 6.2 .8 (right panel) plots short-term yield and SSB versus Fbar. The detailed output by age group, assuming F status quo for 2015-2017, is given in Table 6.2.15 for landings and discards. Under this scenario, projected landings for 2015 and 2016 are 1363 and 1392 t, respectively. Projected discards for the same years are 436 and 393 t .

Under F status quo, projected SSB values for 2016 and 2017 are about 6462 t in 2016 and 6075 t in 2017.

The contributions of recent year classes to the projected landings and SSB are presented in Table 6.2.16 (under F status quo). The year classes for which GM90-12 recruitment is assumed contribute in a $18 \%$ to catches in 2016 and with a $41 \%$ to SSB in 2017.

### 6.2.5.2 Yield and biomass per recruit analysis

The analysis is conducted following the Stock Annex specifications and results presented in Table 6.2.17. The left panel of Figure 6.2 .8 plots yield-per-recruit and SSB-perrecruit versus Fbar.

Under F status quo (Fbar $=0.19$ for landings and Fbar=0.11 for discards), yield-per-recruit is 0.02 kg for landings and 0.01 kg for discards and SSB-per-recruit is 0.12 kg . Assuming GM90-12 recruitment of 44 million, the equilibrium yield would be around 1080 t of landings and 375 t of discards, with an SSB value of 5345 t .

### 6.2.5.3 Biological reference points

The stock-recruitment time series is plotted in Figure 6.1.9. See Stock Annex for more information about Biological reference points.

The BRP are:

|  | Type | Value | Technical basis |
| :--- | :--- | :--- | :--- |
| MSY | MSY Btrigger | 4600 t | default option; 1.4 Blim |
| Approach | FMSY | 0.17 | Fmax as FMSY proxy |
|  | Blim | 3300 t | Bloss in the 2014 benchmark assessment |
| Precautionary | Bpa | 4600 t | default option; 1.4 Blim |
| Approach | Flim |  |  |
|  | Fpa |  |  |

### 6.2.6 Comments on the assessment

Two commercial fleets (SP-LCGOTBDEF-1 and SP-LCGOTBDEF-2) and the Spanish survey (SpGFS-WIBTS-Q4) were used for tuning. The commercial fleet data used for tuning corresponds to ages 3 and older, which are not well represented in the survey. The Spanish survey covers a large part of the distribution area of the stock. The survey appears to have been quite good at tracking cohorts.

With the new settings, discards data and new tuning fleets, the model converges. It seems that the convergence issue is solved for this stock.

Comparison of this assessment with the one performed in 2014 shows minor differences except for the recruitment in recent years which have been revised upward (Figure 6.2.10).

### 6.2.7 Management considerations

This assessment indicates that SSB decreased substantially between 1988 and 2001, the year with lowest SSB, and that there has been a smooth increasing trend from 2001 to present. Fishing at status quo F during 2015 and 2016 would result in some biomass decrease from the 2014 value for 2015, and a similar value for 2016.

There is no evidence of reduced recruitment at low stock levels.
As with L. whiffiagonis, it should be noted that four-spot megrim (L. boscii) is caught in mixed fisheries, and management measures applied to this species may have implications for other stocks. Both species of megrim are subject to a common TAC, so the joint status of these species should be taken into account when formulating management advice.

### 6.3 Combined Forecast for Megrims (L. whiffiagonis and L. boscii)

Figure 6.3.1 plots total international landings and estimated stock trends for both species of megrim in the same graph, in order to facilitate comparisons. The two species of megrim are included in the landings from ICES Divisions VIIIc and IXa. Both are taken as by-catch in mixed bottom trawl fisheries.
Assuming status quo F for both species in 2015 (average of estimated F over 2012-2014, corresponding to Fbar= 0.25 for landings and Fbar=0.02 for discards for L. whiffiagonis and Fbar $=0.19$ for landings and Fbar=0.11 for discards for L. boscii), Figure 6.3 .2 gives the combined predicted landings for 2016 and individual SSB for 2017, under different multiplying factors of their respective status quo F values. The combined projected values for the two species have been computed as the sum of the individual projected values obtained for each species separately under its assumed exploitation pattern. As
usual, the exploitation pattern for each species has been assumed to remain constant during the forecast period.

At status quo F (average F over 2012-2014) for both species, predicted combined catches in 2016 are 1673 t and individual SSBs in 2017 are 911 t for L. whiffiagonis and 6075 t for L. boscii.

Extended Survivors Analysis
Four spot megrim (L. boscii) Division VIIIc and IXa
CPUE data from file fleetb.txt
Catch data for 29 years. 1986 to 2014. Ages 0 to 7.

| Fleet | First Last |  |  |  |  |  |  |
| :--- | :---: | :---: | :---: | :---: | :---: | :---: | ---: | ---: |
|  | yearyear | First <br> age | Last <br> age | Alpha |  | Beta |  |
| SP-LCGOTBDEF1 | 1986 | 2014 | 3 | 6 | 0 | 1 |  |
| SP-LCGOTBDEF2 | 2000 | 2014 | 3 | 6 | 0 | 1 |  |
| SP-GFS | 1988 | 2014 | 0 | 6 | 0.75 | 0.83 |  |

Time series weights:
Tapered time weighting not applied

Catchability analysis:
Catchability independent of stock size for all ages

Catchability independent of age for ages $>=5$

Terminal population estimation :
Survivor estimates shrunk towards the mean F
of the final 5 years or the 3 oldest ages.
S.E. of the mean to which the estimates are shrunk $=1.500$

Minimum standard error for population
estimates derived from each fleet $=.300$

Prior weighting not applied

Tuning converged after 36 iterations

Regression weight

Fishing mortalities

## $7 \quad$ Bay of Biscay Sole

Type of assessment in 2014: update.
Data revisions this year: Compared to last year assessment, there is only very limited change in data due to small revisions of 2013 landings and of 2013 commercial LPUE and survey CPUE.

### 7.1 General

### 7.1.1 Ecosystem aspects

See Stock Annex

### 7.1.2 Fishery description

See Stock Annex

### 7.1.3 Summary of ICES advice for 2015 and management applicable to 2014 and 2015

## ICES advice for 2014:

Since 2010 the ICES advice is to decrease the fishing mortality step by step to the FMSY ( 0.26 for the Bay of Biscay sole) until 2015.

The advice provided for 2015: ICES advises on the basis of the transition to the MSY approach that catches in 2015 should be no more than 2407 tonnes. All catches are assumed to be landed.

## Management applicable to 2014 and 2015

The sole landings in the Bay of Biscay are subject to a TAC regulation. The 2014 TAC was set at 3800 t and the 2015 TAC is the same at 3800 t . The minimum landing size is 24 cm and the minimum mesh size is 70 mm for trawls and 100 mm for fixed nets, when directed on sole. Since 2002, the hake recovery plan has increased the minimum mesh size for trawl to 100 mm in a large part of the Bay of Biscay but since 2006 trawlers using a square mesh panel were allowed to use 70 mm mesh size in this area.

Since the end of 2006, the French vessels must have a Special Fishing Permit when their sole annual landing is above 2 t or be allowed to have more than 100 kg on board.

The Belgian vessel owners get monthly non transferable individual quota for sole and the amount is related to the capacity of the vessel.

A regulation establishing a management plan was adopted in February 2006. The objective was to bring the spawning stock biomass of Bay of Biscay sole above the precautionary level of 13000 tonnes in 2008 by gradually reducing the fishing mortality rate on the stock. Once this target is reached, the Council has to decide on a long-term target fishing mortality and a rate of reduction in the fishing mortality for application until the target has been reached. However, although the stock was estimated above the SSB target in 2008 by ICES in 2009, the long-term target fishing mortality rate and the associated rate of reduction have not yet been set.

### 7.2 Data

### 7.2.1 Commercial catches and discards

The WG estimates of landings and catches are shown in Table 7.1a. The WG landing estimates are the figure obtained by crossing auction sales, available logbooks and data communicated by the administrations of countries involved in the Bay of Biscay sole fishery. The French catches are predominant. Since 2005, the same method has been used to estimate them and, because they are nearly exclusively landed in Bay of Biscay harbours, the record of the auction sales allows us to consider that the reliability of their estimates is satisfactory for the full time-series.

The official landings are lower up to 2008 than the WG landings estimates but they become largely higher in 2009-2010 because since 2009, a new method has been implemented to calculate the French official landings. This important discrepancy in 20092010 was likely caused by some assumptions in the algorithm implemented to calculate French official landings in these years which was modified in 2011. Consequently the official and the WG landing estimates are closer since 2011. However, the WG method to estimate landings is considered to continue to provide the best available estimates of the landing series.

The 2013 landings estimate was revised to 4235 t , this is less than a $0.1 \%$ increase.
In 2002, landings increased to 5486 t due to very favourable weather conditions for the fixed nets' fishery (frequent strong swell periods in the first quarter). In the absence of such apparently rare conditions, the landings in 2003-2008 ranged between 4000 t and 4800 t before falling to 3650 t in 2009 and increasing to 4632 t in 2011 (Table 7.1a).

The 2014 landings figure ( 3934 t) is 12.7 \% above the landings predicted by the 2014 WG at status quo mortality ( 3435 t ).

Discards estimates were provided for the French offshore trawler fleet from 1984 to 2003 using the RESSGASC surveys. Because these estimates depend largely on some questionable hypothesis, their monitoring was not continued in 2004 and they are no longer used in the assessment. However, this survey allowed affirmation that the discards of offshore trawlers are low at age 2 and above. This low level has been confirmed by observations at sea in recent years. These observations have also shown that discards of beam trawlers and gillnetters are generally low but that the inshore trawlers fleet may have occasionally high discards of sole. Unfortunately, they are difficult to estimate because the effort data of inshore trawlers are not precise enough to allow estimating them by relevant areas. However, the French and Belgian discards data should be analysed as soon as possible to investigate if these difficulty can be circumvented before a future benchmark.

### 7.2.2 Biological sampling

The quarterly French sampling for length compositions is by gear (trawl or fixed net) and by boat length (below or over 12 m long). The split of the French landings in these components is made as described in Stock Annex. The 2013 split was slightly revised because of the very small correction in the database (Table 7.1 b ).

Length compositions are available on a quarterly basis from 1984 for the French fleets and from 1994 for the Belgian beam trawlers. The 2014 sampling level is given in table 1.3 (section 1). The French length distributions are shown on Figures 7.1 a to d from 1984 onwards. The relative length distribution of landings in 2014 is shown by country in Table 7.2.

Even though age reading from otoliths now uses the same method as in France and Belgium (see Stock Annex), the discrepancy between French and Belgian mean weight at age, noticed by preceding WGs, are still present. Work was carried out in the beginning of 2012 (PGCCDBS, 2012) to compare the age reading methods. The conclusion is that there was no bias between readers from the three countries using otoliths prepared with the staining technique. All readers produced the same age estimates (i.e. no bias) of otoliths with or without staining.

However, a likely effect of the weight at age samples process may also be presumed (weight-length relationship used in France and straight estimate in Belgium) and should be investigated. International age compositions are estimated using the same procedure as in previous years, as described in Stock Annex. International mean weights at age of the catch are French-Belgian quarterly weighted mean weights. The catch numbers at age are shown in Table 7.3 and Figures 7.2 a \& b, and the mean catch weight at age in Table 7.4.

### 7.2.3 Abundance indices from surveys

Since 2007, a new beam trawl survey (ORHAGO) is carried out by France to provide a sole abundance index in the Bay of Biscay. This survey is coordinated by the ICES WGBEAM.

At the 2013 meeting of the WGBEAM 2013, several CPUE series were compared. The one based on all the reference stations and carried out by daylight was estimated to provide the abundance index to retain for the Bay of Biscay sole.

The 2013 WGHMM assessment was carried out according to a 2013 revised stock annex, which adds the ORHAGO survey to the tuning files. This was a consequence of the interim Benchmark during the WGHMM 2013 who considered that the addition of the survey tuning fleet appears to be useful to the assessment.

In 2014 the survey vessel was changed, however the main change is in the way the gear is attached to the boat which provides more stability to the beam trawl.

The figure 7.3 shows the ORHAGO time series by age group excepted at age 0 , for which the ORHAGO series is not considered to provide a reliable abundance index. Following the 2013 year class to 2014, the results are consistent because we can track the strong 2012 cohort in 2014, wich is the highest value of the series. The trend on the LPUE (figure 7.4) shows an increase for the others commercial LPUE as for ORHAGO. Regarding this, the WG agreed to retain the ORHAGO abundance indices in the assessment.

### 7.2.4 Commercial catch- effort data

The French La Rochelle and Les Sables trawler series of commercial fishing effort data and LPUE indices were completely revised in 2005. A selection of fishing days (or trips before 1999) was made by a double threshold (sole landings $>10 \%$ and nephrops landings $<=10 \%$ ) for a group of vessels. The process is described in the Stock Annex.

The risk that the sole $10 \%$ threshold may lead to an underestimate of the decrease in stock abundance was pointed out by RG in 2010. This general point is acknowledged by this working group. However in this particular case using the knowledge about the fishery this threshold was set to avoid the effect of changing target species, which may also affect the trend in LPUE. Indeed, the choice of target species may affect effort repartition between sole major habitat and peripheral areas where sole abundance is lower. Because $10 \%$ is a minimum for sole percentage in catch when carrying out mixed
species trawling on sole grounds, according to fishermen, this percentage was retained to ensure that sole LPUE are not driven by a fishing strategy evolution (the targeting of cephalopods more particularly).

The La Rochelle LPUE series (FR-ROCHELLE) shows a decreasing trend from 1990 to 2001. Later on, the series does not exhibit any trend but some up and down variations (Table 7.5.a and Figure 7.4). The Les Sables d'Olonne LPUE series (FR-SABLES) shows also a declining trend up to 2003. Thereafter, it shows a short increase in 2004-2005 but the trend is flat from 2005 onwards.

Two new series of tuning were added to the assessment according to the WKFLAT 2011: the Bay of Biscay offshore trawler fleet ( $14-18 \mathrm{~m}$ ) in the second quarter (FR-BB-OFF-Q2) and the Bay of Biscay inshore trawler fleet ( $10-12 \mathrm{~m}$ ) in the fourth quarter (FR-BB-IN-Q4) for 2000 to the last year. A selection of fishing days was made by a double threshold (sole landings $>6 \%$ and nephrops landings $<=10 \%$ ) The process is described in the Stock Annex.

Unfortunately, the fishing effort for the FR-BB-OFF-Q2 is not available for 2013 and 2014. This is due to the use of the electronic logbooks, for which the fishing effort is not a required value. This data is not well exported in the official database, and the majority of the fishing effort is equal to 1 . Therefore, the commercial LPUE could not be calculated for this fleet and year.

However, LPUE for the FR-BB-IN-Q4 fleet is provided using paper logbooks which are still used by this fleet. Its LPUE trend shows an increase from 2013 to 2014 (Figure 7.4).

The Belgian LPUE series was relatively constant from 1990 to 1996, declining severely until 2002 but increased in 2003 to return to the 1997-2000 level. Later on, its trend was flat until 2009, but it changed to an increasing one in 2010. The last value is higher than 2013 but still close to the 2004 value.

For the ORHAGO survey, the trend of the CPUE are similar to those of the commercial tuning fleets available in recent years and, more particularly, it is close to the trend of the Belgian beam trawler fleet and it also shows an increase from 2013 to 2014.

Consequently, all the LPUE and CPUE series available show an increase in the last year of the series.

### 7.3 Assessment

### 7.3.1 Input data

See stock annex

### 7.3.2 Model

As in previous years, the model chosen by the Group to assess this stock was XSA.
The age range in the assessment is 2-8+, as last year assessment.
The year range used is 1984-2014.

## Catch-at-age analysis and Data screening

The results of exploratory XSA runs, which are not included in this report, are available in ICES files.

A separable VPA was run to screen the catch-at-age data. The same settings as last year were used: terminal $F$ of 0.6 on age 4 and terminal $S$ of 0.9 . There were no anomalous residuals apparent in recent years.

Four commercial LPUE series are used in the assessment: La Rochelle offshore trawlers (FR-ROCHELLE) and Les Sables d'Olonne offshore trawlers (FR-SABLES) 1991 to 2009, the Bay of Biscay offshore trawlers in the second quarter (FR-BB-OFF-Q2) 2000 to 2012 and the Bay of Biscay inshore trawlers in the last quarter (FR-BB-IN-Q4) 2000 to last year. The data for these four tuning series are in table 7.6.

The table below summarizes the available information on the commercial tuning fleets and the survey.

| FLEET TYPE | ACRONYM | PERIOD | AGE | RANGE |
| :--- | :--- | :--- | :--- | :--- |
| LANDING CONTRIBUTION |  |  |  |  |
| Offshore otter trawlers | FR-SABLES | $1991-2009$ | $1-8$ | $<1 \%$ |
| Offshore otter trawlers | FR-ROCHELLE 1991-2009 | $1-8$ | $<1 \%$ |  |
| Inshore otter trawlers | FR-BB-IN-Q4 | $2000-2014$ | $1-8$ | $<1 \%$ |
| Offshore otter trawlers | FR-BB-OFF-Q2 | $2000-2012$ | $1-8$ | $<1 \%$ |
| Beam trawler survey | FR-ORHAGO | $2007-2014$ | $0-8$ | $0 \%$ |

XSA tuning runs (low shrinkage s.e. $=2.5$, no taper, other settings as in last year tuning) were carried out on data from each fleet individually. The results show no trend and small residuals for all fleets (Figure $7.5 \mathrm{a} \& \mathrm{~b}$ ) except for the FR-BB-OFF-Q2 for age 2 in 2009, 2010 and 2011 and for FR-ORHAGO at age 5 in 2007 and at age 6 in 2008, 2010 and in 2014.

## Result of XSA runs

The final XSA was run using the same settings than in last year assessment.
The Figure 7.2 b shows a distribution of catches at age, between age 2 and 6 . The strong age 4 and 5 last year are now found in the age 5 and 6 this year. This figure shows too a strong age 2 which is the most important of this year's series.

As in last year's assessment, the weight of the ORHAGO survey age estimate is major, far above the weight of other fleets from age 2 to 6 (Table 7.7), 97.5 \% for age 2, 78.2 \% for age 3 , and $72 \%$ for age 4 for example.

The results are given in Table 7.7. The log-catchability residuals are shown in Figure $7.5 \mathrm{a} \& \mathrm{~b}$ and retrospective results in Figure 7.6. The retrospective pattern shows a very small $F$ overestimation and a small SSB overestimation in 2013. The SSB overestimation is linked to the F overestimation at age 5 and 6 .
Because of the lack of the FR-BB-OFF-Q2 2014 abundance indices in the tuning data, the estimated survivors at age 2 are only based on the ORHAGO survey.
At age 3, the only one commercial fleet estimated survivors to have a significant weight is the FR-BB-INQ4 (around 20\%) and it increases by $42 \%$ at age 7. The FR-BB-OFF-Q2 has less weight than the others fleets, the maximum is at age 6 at around $15 \%$. The two discontinuied commercial fleets FR-SABLES and FR-ROCHELLE have minor weight and only at age 7 (less than $0.1 \%$ ). At age 6 , the fleets FR-BB-IN-Q4 and FR-ORHAGO have more or less the same estimated survivors around $40 \%$.

Fishing mortalities and stock numbers at age are given in Tables 7.8 and 7.9 respectively. The results are summarised in Table 7.10. Trends in yield, F, SSB and recruitments are plotted in Figure 7.7. Fishing mortality in 2014 is estimated by XSA to have been at 0.48 . Fishing mortality was 0.45 in 2012 , and 0.47 in 2013. The fishing mortalities in 2011 and 2012 are a slightly higher than the value calculated at the last year's working group.

### 7.3.2.1 Estimating year class abundance

In this year's assessment the retrospective analyses shows that the 2012 and 2013 recruitments were well estimated and that the recruitments are confirmed to be at a low level. The group therefore considers that, with the inclusion of the ORHAGO survey, the estimate of the recruitment for last year (2014 in this year's assessment) has improved compared to previous assessment and decided to keep the value estimated by the assessment model.

The WG agreed to keep this calculation of the GM (1993 to $n-2$ ) to be homogeneous with the previous assessment.

Recruitment at age 2

| Year class | Thousands | Basis | Survey | Commercial | Shrinkage |
| :--- | :--- | :--- | :--- | :--- | :--- |
| 2012 | 25770 | XSA | $97.5 \%$ | $0 \%$ | $2.5 \%$ |
| 2013 \& subsequent | 21825 | GM(93- <br> $12)$ |  |  |  |

## Historic trends in biomass, fishing mortality and recruitment

A full summary of the time series of XSA results are given in Table 7.10 and illustrated in Figure 7.7.

Since 1984, fishing mortality gradually increased, peaked in 2002 and decreased substantially the following two years. It increased in 2005 and, later on stabilised at around 0.44 ( $\mathrm{Fpa}=0.42$ ) until 2012, this year it is estimated to be the highest value since 2009 (0.48).

The SSB trend in earlier years increases from 12300 t in 1984 to 16400 t in 1993, afterwards it shows a continuous decrease to 9600 t in 2003. After an increase between 2003 and 2006, the SSB remains close to 11300 t from 2007 to 2009 . Since 2010, the SSB although above Bpa ( 13000 t ) has been decreasing since 2012. The SSB value for 2013 has been reassess from 13700 t to 13200 t. The 2014 SSB is estimated to 10576 t, lower (17\%) than the estimated value from WGBIE 2014.

The recruitment values are lower since 1993. Between 2004 and 2008 the series is stable around 17 or 18 million and the 2007 year class is the highest value since 1984. The 2010 and 2011 values are closed to the GM93-12 (21.8 million). However, the 2012 and 2013 values are the lowest of the series ( 11.3 million and 12.2 million respectively).

### 7.3.3 Catch options and prognosis

Although there is a slight increase in F for the last three years, the WG did not consider that there was a trend (Figure 7.7). Thus, the exploitation pattern is the mean over the period 2012-2014 (for age 2 and above). This status quo F is estimated at 0.46 for the run.

The recruits at age 2 from 2015 to 2017 are assumed equal to GM93-12. Stock numbers at age 3 and above in 2015 are the XSA survivors estimates.

Weights at age in the landings are the 2012-2014 means using the new fresh/gutted transformation coefficient of French landing which was changed from 1.11 to 1.04 in 2007. Weights at age in the stock are the 2012-2014 means using the old fresh/gutted transformation coefficient of French landing (1.11). The predicted spawning biomass is consequently still comparable to the biomass reference point of the management plan.

### 7.3.3.1 Short term predictions

Input values for the catch forecast are given in Table 7.11.
The landings forecasts (Table 7.12) is 3939 t in 2015 (TAC is set at 3800 t ), more or less the same than the 2014 landings (3934 t).

Assuming recruitment at GM93-12, the SSB is predicted to increase to 12000 t in 2015 and increase to 12807 t in 2016, fishing at status quo F in 2015. It will continue to grow at status quo F , to reach 13390 t in 2017 (Tables 7.12 and 7.13).

The proportional contributions of recent year classes to the landings in 2016 and to the SSB in 2017 are given in Table 7.14. Year classes for which GM93-12 recruitment has been assumed (2013 to 2015) contribute 48.6 \% of the 2016 landings and $57.7 \%$ of the 2017 SSB.

### 7.3.3.2 Yield and Biomass Per Recruit

Results for yield and SSB per recruit conditional on status quo F, are given in Table 7.15 a \& b, and in Figure 7.8. The $\mathrm{F}_{\mathrm{sq}}(0.46)$ is $2 \%$ below $\mathrm{F}_{\max }(0.45)$ and $58 \%$ higher than
$\mathrm{F}_{0.1}$ (0.2). Long-term equilibrium landings and SSB (at F status quo and assuming GM recruitment) are estimated to be 4533 t and 14311 t respectively (Table 7.15a \& b).

### 7.3.4 Biological reference points

WGHMM 2010 proposals for MSY approach reference points are given below with technical basis with the value adopted for the precautionary approach reference points:

|  | Type | Value | Technical basis |
| :--- | :--- | :--- | :--- |
| MSY | MSY <br> Btrigger | 13000 t | Bpa |
| Approach | FMSY | 0.26 | Fmax (as estimated by WGHMM 2010) because no <br> stock-recruitment relationship, limited variations <br> of recruitment, Fishing mortality pattern known <br> with a low uncertainty |
| Precautionary | Bpa | 13000 n | Not <br> defined <br> when SSB is below 13 000 t, based on the historical <br> development of the stock. |
| Approach | Flim | 0.58 | Based on the historical response of the stock. |
|  | Fpa | 0.42 | Flim * 0.72 |

The basis for setting Flim was kept (historical response of the stock) and its value remains coherent with the historical SSB trend. Consequently, Fpa is unchanged.

The fishing mortality pattern is known with a low uncertainty because of the limited discards and the satisfactory sampling level of the catches.

The WKFLAT 2011 decided that Fmax remains unchanged as well as FMSY which is set to Fmax. This year the $\mathrm{F}_{\max }$ is as the same level than the WG 2014 after an increase in 2011, 2012 and 2013 estimates. The working group carried out a new examination of the MSY reference point. Following recommendations from WKMSYREF3, it was decided to use the software PlotMSY and Eqsim.

## EqSim

EqSim (stochastic equilibrium reference point software) provides MSY reference points based on the equilibrium distribution of stochastic projections. Productivity parameters (i.e. year vectors for natural mortality, weights-at-age, maturities, and selectivity) are re-sampled at random from the last 3-5 years of the assessment (although there may be no variability in these values). Recruitments are resampled from their predictive distribution. The software also allows the incorporation of assessment/advice error. Uncertainty in the stock-recruitment model is taken into account by applying model averaging using smooth AIC weights (Buckland et al. 1997). The method is described in more detail in Annex 8 of ICES WGMG (2013).

The main inputs for this software are $B_{p a}$ and $B_{l i m}$. For $B_{l i m}$ which is currently not defined for sole, the WG decided to use a value close to Bloss $=9600 \mathrm{t}$.

## PlotMSY

This software (equilibrium approach with variance) is intended to provide robust estimation of deterministic (i.e. no future process error) MSY estimates that could be applied easily and widely. It fits three stock-recruit functions, namely the Ricker,

Beverton-Holt, and a smooth Hockey-stick (Mesnil and Rochet, 2010), to estimate MSY quantities. Uncertainty in MSY estimates is characterised by MCMC sampling of the stock-recruit parameters and sampling from the distributions of other productivity parameters (i.e. natural mortality, weights-at-age, maturities, and selectivity).

Stock-recruit model uncertainty is taken into account by model averaging of the three functions. ICES WGMG (2013), Annex 7 provides a more detailed description of the method.

The main inputs for this software are $\mathrm{F}_{\mathrm{pa}}, \mathrm{Fl}_{\mathrm{im}}, \mathrm{B}_{\mathrm{pa}}$ and $\mathrm{Blim}_{\mathrm{lim}}$. The number of MCMC fits calculated and used for confidence interval was set to 1000 .

## Results of analysis

For the two software results, the stock-recruitment values obtained from the assessment do not show any clear stock-recruitment signal to allow a clear estimation of a stock-recruitment curve (figure 7.9 et 7.10). There are no data sufficiently close to the origin to allow an understanding of what may happen at lower stock biomasses.

Combinig all SRR, the specified weight are different for Eqsim and plotMsy (table 7.16 and 7.17). PlotMsy result gives the maximum weight for Beverton-Holt and Eqsim for Segreg model.

For the EqSim SRRplot (figure 7.9) the breakpoint of the smooth Hockey-Stick model is estimated at a SSB around 14500 tonnes and for the plotMsy SRRplot (figure 7.10) it is estimated around 12500 t .

The equilibrium yield and SSB based on the three stock and recruitment models estimates are presented in Figures 7.11 to 7.13 for the plotMsy results, together with box plots of $\mathrm{F}_{\text {MSY }}$ and $\mathrm{F}_{\text {crash, }}$ and proxies for $\mathrm{F}_{\text {mSy }}$ based on the yield per recruit ( $\mathrm{F}_{\max }, \mathrm{F}_{0.1}$ ), and based on SSB per recruit ( $\mathrm{F}_{30 \%}$ and $\mathrm{F}_{35 \%} \mathrm{SPR}$ ). Values of $\mathrm{F}_{\mathrm{MSY}}$ reference points estimated for the 3 stock recruitment relationships are presented in Table 7.18 for plotMsy and table 7.19 for Eqsim. The plotMsy table shows that the Fmsy calculated for each $\mathrm{S} / \mathrm{R}$ relationship are quite different: 0.38 for Ricker model, 0.47 for Hockey stick and 0.24 for Beverton-Holt model close to current Fmsy. For Eqsim this mean Fmsy value is estimated at 0.26 (=current Fmsy).

The figure 7.14 shows the probability of SSB being below $\mathrm{B}_{\lim }$ at different values of F using the weighted combination of stock-recruit models (plotMsy). The fishing mortalities associated with a $5 \%$ probability for SSB to fall below Blim was estimated at 0.41, (close to Fpa) and this value is higher (0.48) for EqSim (figure 7.15 and 7.16)

The Fmsy estimated with the combination of the three $\mathrm{S} / \mathrm{R}$ relationships is equal to 0.36 for PlotMsy and equal to 0.32 for EqSim (Table 7.19 and 7.20, figure 7.16).

It must be noted also that the current $\mathrm{F}_{\max }$ is estimated at 0.46 by xsa, which is above the fishing mortalities associated with a $5 \%$ probability for SSB to fall below $\mathrm{Blim}_{\mathrm{lim}}$. Fishing at $\mathrm{F}_{\max }$ would thus be in conflict with precautionary considerations.

In 2010 the $\mathrm{F}_{\text {msy }}$ value ( $=0.26$ ) was estimated as a proxy of $\mathrm{F}_{\max }$ based on the relative stability of this value in previous years. This $\mathrm{F}_{\max }$ has increased since 2012 (0.31) until this year (0.46). The WG considers now that the current $\mathrm{F}_{\text {mSY }}$ proxy may no longer be appropriate. However, as there is no clear stock recruitment relationship for this stock and as the two methods used during the WG are providing different results, the WG considers that further work is needed in order to make proposals for a revision of FMSY for the Bay of Biscay sole.

### 7.3.5 Comments on the assessment

## Sampling

The sampling level (table 1.3, section 1) for this stock is considered to be satisfactory.
The ORHAGO survey provides information on several year classes at age 2 . This series is now used in the assessment. At other ages, it is particularly useful to have a survey in the tuning file because the new use of electronic logbooks has caused some obvious wrong recordings of effort which limit available commercial tuning data in 2012 and 2013 and the lack of FR-BB-OFF-Q2 2013 and 2014 abundance indices.

Stopping the use of fleets of La Rochelle and Les Sables tuning series led to a paucity of information at age 2 in 2013, which were only provided by the Offshore Q2 tuning fleet (when the data was available). That is no more the case with incorporation of the ORHAGO survey in the assessment.

The same age reading method is now adopted by France and Belgium, however a discrepancy still exist between French and Belgian weights at age which has to be investigated.

## Discarding

Available data on discards have shown that discards may be important at age 1. Discard at age 2 were assumed to be low in the past because the high commercial value of the sole catches but there are some reports of high-grading practices due to the landing limits adopted by some producers' organisations. The data available for discards do not seem representative to use them in the assessment, but the WKFLAT 2011 and the 2012 review group recommended that further work should include investigation on the monitoring of the inshore trawlers discards.

## Consistency

Since the 2013 assessment, the ORHAGO survey has been included in the tuning fleets. This survey is the only one tuning fleet which provides a recruit index series up to 2013 because no LPUE data are available in 2013 and 2014 for the only one commercial tuning fleet which can also provide a recruitment index. The incorporation of a survey in the assessment is considered to have improved the XSA recruit estimates in the assessment terminal year.

A few more years of survey data may improve our ability to confirm the quality of these estimates. The 2012 and 2013 low recruitment appears to be estimated fairly well by the available tuning series (ORHAGO weight 97.5 \%).

The GM is used only for the 2015 recruitment; this GM estimate has now a lower contribution in predicted landings and SSB. Furthermore, it is worth noting that variability of the recruit series has increased since 2001 and that, in recent period (until 2011), the use of GM estimate has led several times to forecast an increase in SSB which was superior to the one observed in following years.

The retrospective pattern in F shows a very small underestimation in 2013 (Figure 7.6) no more than $1 \%$. The definition of reference groups of vessels and the use of thresholds on species percentage to build the French series of commercial fishing effort data and LPUE indices is considered to provide representative LPUE of change in stock abundance by limiting the effect of long term change in fishing power (technological creep) and of change in fishing practices in the sole fishery.

The figure 7.17 shows the difference between the assessments in 2014 and in 2015. SSB in 2013 is revised slightly lower and F in 2013 revised very slightly higher.

## Misreporting

Misreporting is likely to be limited for this stock but it may have occurred for fish of the smallest market size category in some years. There are some reports of high-grading practices due to the landing limits adopted by some producers' organisations.

## Industry input

The traditional meeting with representatives of the fishing industry was organized in France prior to the WG to present the data used by the 2015 WGBIE to assess the state of the Bay of Biscay sole stock. They have made comments for the Fmsy, they emphasised that the Fmsy needs to be reevaluated. Anecdotial information from industry have highlighted that the abundance of sole in some parts of the Bay of Biscay have increased to levels close to that seen 20 years ago. In order not to use all their yearly quota in the beginning of this year, they had to reduce their fishing effort.

## Management considerations

The assessment indicates that SSB has decreased continuously to 9700 t in 2003, since a peak in $1993(16500 \mathrm{t})$, has increased to 12400 t in 2006 but it remains close to 11700 t thereafter and since 2010 is above 13000 t . It is estimated to be 12012 t (below $\mathrm{B}_{\mathrm{pa}}=$ 13000 t ) in 2015 assuming XSA recruitment value for 2014, but an increase is predicted by the short term prediction, and SSB is assumed to be close to $B_{p a}$ in 2016 and above in 2017.

The (EC) 388/2006 management plan is agreed for the Bay of Biscay sole but a longterm F target has not yet been set. This plan has not been evaluated by ICES.

The WG considers that the current Fmsy proxy may no longer be appropriate. It was not possible to update the value during the working group and the group considers that further work is needed.

(*) for 2007 to 2013, French catch weight at age computed using the new fresh/gutted transformation coefficient (1.04)
Before 2007, the French fresh/gutted transformation coefficient is 1.11
The Belgian fresh/gutted transformation coefficient is 1.04 in 2014

Time series weights :
    Tapered time weighting not applied
    Catchability analysis :
    Catchability independent of stock size for all ages
    Catchability independent of age for ages >= 6
Terminal population estimation :
    Survivor estimates shrunk towards the mean F
    of the final }5\mathrm{ years or the }3\mathrm{ oldest ages.
    S.E. of the mean to which the estimates are shrunk = 1.500
    Minimum standard error for population
    estimates derived from each fleet = . }20
    Prior weighting not applied
    Tuning converged after 75 iterations

## 8 Sole in subdivision VIIIc and IXa

### 8.1 General biology

Common sole (Solea solea) spawning takes place in winter/early spring and varies with latitude starting earlier in the south (Vinagre, 2007) . Larvae migrate to estuaries where juveniles concentrate until they reach approximately 2 years of age and move to deeper waters. In Portuguese waters, sole length of first maturity is estimated as 25 cm for males and 27 cm for females (Jardim, et al, 2011). Sole is a nocturnal predator and therefore more susceptible to be captured by fisheries at night than in daytime. It feeds on polychaetes, molluscs and amphipods. S. solea is abundant in the Tagus estuary and uses this habitat as nursery ground. (Cabral and Costa, 1999)

Recent growth studies based on Solea otolith readings in the Portuguese coast indicate $\operatorname{Linf} 52.1 \mathrm{~cm}$ (females) and 45.7 cm (males) while the growth coefficient (k) estimate of females $(\mathrm{K}=0.23)$ was slightly higher than for males $(\mathrm{k}=0.21)$ and to -0.11 and 1.57 for females and males respectively, (Teixeira and Cabral, 2010). Maximum length observed between 2004 and 2011 from the landings sampling program (PNAB-DCF) attained 60 cm . According to Vinagre (2007) S. solea off the Portuguese coast presents higher growth rates in comparison with the northern European coasts.

### 8.2 Stock identity and possible assessment areas;

There is no clear information to support the definition of the common sole stock for ICES subdivision VIIIc and IXa.

### 8.3 Management regulations (TAC's, minimum landing size)

The minimum landing size of sole is 24 cm . There are other regulations regarding the mesh size for trammel and trawl nets, fishing grounds and vessel's size. A precautionary TAC was set for Solea spp. in ICES divisions VIIIc- e, subareas IX and X.

### 8.4 Fisheries data

Table 8.11 presents all soles species official landings by country, for Division VIIIc and IXa. Table 8.12 indicates only common sole (Solea solea) official landings by Division and country. Figure 8.11 illustrates Solea species (Solea solea, Solea senegalensis and Pegusa lascaris) landings for Divisions VIIIc and IXa.

There is evidence of market solea species misclassification which means solea solea Portuguese official landings might not correspond only to this species but mixed with Solea senegalensis and Pegusa lascaris. Based on harbour length sampling data it is possible to separate the soles complex using scientifically identified proportions of each species: Solea solea, S. senegalensis and Pegusa lascaris, and this was estimated for the landings in Portugal (Division IXa) (Borges, et al., 2014)
Landings length compositions for Solea solea are presented for the Portuguese area (Figure 8.12) (Borges, et al, 2014).

Based on the DCF discard sampling in Portugal discards for Sole (Solea solea) only occur in negligible small amounts due to the minimum landing size or damaged specimens.

### 8.5 Survey data, recruit series

Solea solea is rarely caught in the existing Portuguese bottom trawl research surveys (Jardim et al, 2011). This species may be found along the Portuguese coast mainly from very shallow waters and estuaries up to 100 m depth. To monitor sole species a dedicated independent research survey is necessary.

### 8.6 Biological sampling

In Div IXa, existing biological sampling is based on fishery data from commercial vessels landings.

### 8.7 Population biology parameters and a summary of other research

Solea solea maturity ogives by sex, length-weight relationship, sex-ratio by length based on harbour DCF sampling were presented in 2012 for IXa division (Jardim, et al, 2011).

### 8.8 General problems

In Portugal Solea solea (SOL) is caught together with and other similar species Solea senegalensis (OAL) and Pegusa lascaris (SOS) and there are evidences of misreporting sole (Solea solea) with the other two species. Figure 8.13 indicates the proportion of landings attributed to each species based on harbour DCF-IPMA sampling. It is apparent that the most abundant species in the area is Solea senegalensis (OAL) as reflected by the estimated higher catches, than Solea solea and Pegusa lascaris, based on the scientifically separated species sampling.

## 9 Hake in Division IIIa, Subareas IV, VI and VII and Divisions VIIIa,b,d (Northern stock)

Type of assessment: update (stock benchmarked in 2014), stock on observation list. Data revisions: Spanish Porcupine Ground Fish Survey (SpPGFS-WIBTS-Q4) from 2001 to 2013 was revised. Review Group issues: None.

### 9.1 General

### 9.1.1 Stock definition and ecosystem aspects

This section is described in the Stock Annex.

### 9.1.2 Fishery description

The general description of the fishery is now presented in the Stock Annex.

### 9.1.3 Summary of ICES advice for 2016 and management for 2014 and 2015

ICES advice for 2015
The stock was considered to be above any potential MSY Btrigger. Following the ICES MSY framework implied fishing mortality to be reduced to 0.27 , resulting in landings of 78457 t tones in 2016.

Like the main stocks of the EU, the Northern hake stock is managed by a TAC and quotas. The TACs for recent years are presented below:

| TAC (t) | 2009 | 2010 | 2011 | 2012 | 2013 | 2014 | 2015 |
| :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- |
| IIIa, IIIb,c,d (EC Zone) | 1552 | 1661 | 1661 | 1661 | 2093 | 2466 | 2738 |
| IIa (EC Zone), IV | 1808 | 1935 | 1935 | 1935 | 2438 | 2874 | 3190 |

| VIIIa,b,d,e | 19261 | 20609 | 20609 | 20609 | 25970 | 30610 | 33977 |
| Total Northern Stock <br> [IIa-VIIIabd] | 51500 | 55105 | 55105 | 55105 | 69440 | 81846 | 90849 |

## Management for 2014 and 2015

The minimum legal sizes for fish caught in Sub areas IV-VI-VII and VIII is set at 27 cm total length (30cm in Division IIIa) since 1998 (Council Reg. no 850/98).
From 14th of June 2001, an Emergency Plan was implemented by the Commission for the recovery of the Northern hake stock (Council Regulations N ${ }^{\circ} 1162 / 2001,2602 / 2001$ and $494 / 2002$ ). In addition to a TAC reduction, 2 technical measures were implemented. A 100 mm minimum mesh size has been implemented for otter-trawlers when hake comprises more than $20 \%$ of the total amount of marine organisms retained onboard. This measure did not apply to vessels less than 12 m in length and which return to port within 24 hours of their most recent departure. Furthermore, two areas have been defined, one in Sub area VII and the other in Sub area VIII, where a 100 mm minimum mesh size is required for all otter-trawlers, whatever the amount of hake caught.

There are explicit management objectives for this stock under the EC Reg. No 811/2004 implementing measures for the recovery of the northern hake stock. It is aiming at increasing the quantities of mature fish to values equal to or greater than 140000 t . This is to be achieved by limiting fishing mortality to 0.25 and by allowing a maximum change in TAC between years of $15 \%$.
According to ICES advice for 2012, due to the new perspective of historical stock trends, resulting from the new assessment, the previously defined precautionary reference points are no longer appropriate. In particular, the absolute levels of spawning biomass, fishing mortality, and recruitment have shifted to different scales. As a consequence, the TAC corresponding to the current recovery plan (EC Reg. No. 811/2004) should not be considered, because the plan uses target values based on precautionary reference points that are no longer appropriate.

The initial TAC for 2015 ( 78457 t) was revised upwards ( 90849 t) by the EC after 2014 assessment working group.

### 9.2 Data

### 9.2.1 Commercial catches and discards

Total landings from the Northern stock of hake by area for the period 1961-2014 as used by the WG are given in Table 9.1. They include landings from Division IIIa, Subareas IV, VI and VII, and Divisions VIIIa,b,d, as reported to ICES. Unallocated landings are also included in the table; they are high over the first decade (1961-1970), when the uncertainties in the fisheries statistics were high. In the years 2011, 2012 and 2013, they have increased again due to differences between official statistics and scientific estimations. In 2014, the differences between scientific and official landings decreased greatly which produced a big decrease in unallocated landings. The scientific landings for 2011, 2012 and 2013 were revised before the assessment working group and resulted in an increase of 7910, 10444 and 981 tonnes in landings respectively. The group decided to use scientific revised estimates to carry out the assessment. The unallocated landings were divided by metier using scientific information provided by the research institutes. Table 1 of the Stock Annex provides a historical perspective of the level of aggregation at which landings have been available to the WG.
Except for 1995, landings decreased steadily from 66500 t in 1989 to 35000 t in 1998. Up to 2003, landings fluctuated around 40000 t . Since then, with the exception of 2006, landings have been increasing up to 91525 t in 2014, the highest value since 1961. The landings in 2014 were well above the 2014 TAC ( 81 846t).

The discard data sampling and data availability are presented in the Stock Annex. Table 9.2 presents discard data available to the group from 1999 to 2015. The discards increased significantly in since 2008 to 2013; the total amount of observed discards in 2013 was double of those observed in 2008. The increase was general to all the fleets. However in 2014 the discards decreased in general for all the fleets. It is remarkable the case of gillnetters which did not discard until 2011 and after they have high level of discards only for two years, around 1000 tonnes.

### 9.2.2 Biological sampling

The sampling level is given in Table 1.3.
Length compositions of the 2014 landings by Fishery Unit and quarter were provided by Ireland, France, Scotland, Spain, UK(E\&W) and Denmark.

Length compositions samples are not available for all FUs of each country in which landings are observed (see Stock Annex). Only the main FUs are sampled (Table 9.3).

### 9.2.3 Abundance indices from surveys

Four surveys provide relative indices of hake abundance over time. The French RESSGASC survey was conducted in the Bay of Biscay from 1978 to 2002, the EVHOE-WIBTS-Q4 survey conducted in the Bay of Biscay and in Celtic Sea with a new design since 1997, the SpPGFS-WIBTS-Q4 survey conducted on the Porcupine Bank since 2001, and the Irish Groundfish Survey (IGFS-WIBTS-Q4) beginning in 2003 in the west of Ireland and the Celtic Sea. A brief description of each survey is given in the Stock Annex. Figure 9.1 present the abundances indices obtained for these surveys.

From 1985 until the end of the survey in 2002, the index from RESSGASC followed a slightly decreasing trend. The index from 2002 is not considered reliable and is not presented on the figure.
Throughout the available time series, the abundance index provided by EVHOE-WI-BTS-Q4 showed four peaks in 2002, 2004, 2008 and 2012. The index obtained in 2012 reached the highest value of the series, $193 \%$ higher than previous year. Since then the index shows a decreasing trend and accumulates a decrease of $78 \%$.

The abundance index provided by IGFS-WIBTS-Q4 is consistent with EVHOE WIBTSQ4 survey over recent years. It showed a peak in 2008 and the abundance index obtained in 2012 achieves the higher value of the series, $268 \%$ higher than previous year index. The accumulate decrease since 2012 in this case is equal to $86 \%$.

SpPGFS-WIBTS-Q4 survey is conducted on Porcupine's Bank since 2001. The abundance index follows an increasing trend since 2003, reaching its highest value in 2009 and slightly decreases in 2010 and 2011. The abundance index has an increasing trend since 2012 and it accumulates an increase of $218 \%$. The peaks detected by EVHOE-WIBTS-Q4 and IGFS-WIBTS-Q4 are detected in this survey one year after. This is consistent with the fact that this survey catches bigger individuals.

The spatial distribution of the EVHOE-WIBTS-Q4 index for hakes from 0 to 20 cm is given in Figure 9.4 for the most recent years. It is apparent from this figure that interannual variations in abundance are different between areas (VII and VIII). In 2012, both areas display large abundance, even higher than in 2008, another year with high abundance index over recent years. Since 2012 the recruitment abundance shows a decreasing trend especially in the Celtic sea.

### 9.2.4 Commercial catch-effort data

A description of the commercial LPUE indices available to the group is given in the Stock Annex. They are not used in the assessment model.

Effort and LPUE data for the period 1982-2012 are given in Table 9.4 and Figure 9.2.
Since the start of the time series the effort of A Coruña and Vigo trawler fleets operating in Subarea VII show a decreasing trend. The LPUE of A Coruña trawlers has fluctuated, with an increasing trend reaching its maximum value in 2011 and after a sharp decreased in 2012 and 2013 it slightly increased in 2014. Over the same period, LPUE from Vigo trawlers operating in Subarea VII followed a slightly decreasing trend, becoming less variable during the last 15 years. It must be taken into account that while A Coruña trawl fleet is targeting hake, the Vigo trawl fleet is directed to megrim, taking hake only as bycatch.

LPUE from Ondarroa pair trawlers operating in Divisions VIIIa,b, shows an increasing trend until 2009. The increase in LPUE in 2008 and 2009 was very high, especially in 2009. Until 2012 the LPUE decreased, although not to the low levels of the beginning of the time series. In 2013 it increased slightly again followed by a decrease in 2014. Since 1999 the effort has a decreasing trend.

## Assessment

This is an update assessment.

### 9.2.5 Input data

See Stock Annex (under "Input data for SS3").

### 9.2.6 Model

The Stock Synthesis 3 (SS3) assessment model (Methot and Wetzel 2013) was selected for use in this assessment. Model description and settings are presented in the Stock Annex (under "Current assessment" for model description and "SS3 settings (input data and control files)" for model settings).

### 9.2.7 Assessment results

Residuals of the fits to the surveys $\log$ (abundance indices) are presented in Figure 9.6. The greater part of the upward trend, until 2012, in relative abundance observed in all three contemporary trawl surveys (EVHOE-WIBTS-Q4, SpPGFS-WIBTS-Q4 and IGFS-WIBTS-Q4) has been captured by the model but there is still some residual trend apparent in the graphs. Pearson residuals of their length frequency distributions show a "fairly random" behaviour with no particular trend or lack of fit (Figure 9.6, where blue and red circles denote positive and negative residuals, respectively). Residuals of the length frequency distributions of the commercial fleets landings and discards (not presented in this report but available on the Share-point) show some patterns, as mentioned in the benchmark report (ICES, 2014a).
The assessment model includes estimation of size-based selectivity functions (selection pattern at length) for commercial fleets and for population abundance indices (surveys). For commercial fleets total catch is subsequently partitioned into discarded and retained portions. Figure 9.7 presents selectivity (for the total catch; solid lines) and retention functions by fleet (dashed lines) estimated by the model. The selection curve is assumed constant over the whole period for all the fleets except for that operating outside areas VII and VIII (the others fleet). For the Spanish trawl fleets in VII, three retention functions are estimated, one for years 1978-1997 (black), a second one for 1998-2009 (red) and a third one for 2010-present (green). For the Spanish trawl fleets in VIII, two retention functions are estimated one for years 1978-1997 and a second one for 1998-present The change in retention in 1998 for both trawl fleets was clearly noticed when examining the length frequency distributions of the landings and might be due to a stricter enforcement of the minimum landing size. The most recent change in retention of Spanish trawl fleet in VII was motivated by the observed change in the mean size of discards from 23.6 cm before 2010 to 28.8 cm after that year. For the French trawlers targeting Nephrops in VIII, the same retention function is assumed throughout the entire assessment period (1978-present). For the other fleet both selection and retention curves are considered constant until 2002 and are allowed to vary from year to year since then. The variation is modelled using a random walk as described in the stock annex. The assessment currently assumes that the other commercial fleets do not
discard fish, although this assumption should be revised as more information on discards becomes available. It is noteworthy the high amount of discards (> 1000 tonnes) of gillnetter fleet in VII and VIII in the last two years. Before 2012 the discards of this fleet were considered negligible..
The retrospective analysis (Figure 9.8) shows that for F and SSB the model results are sensitive to the exclusion of recent data. The inclusion of 2012 data provoked a revision upwards of the SSB and downwards of the fishing mortality. The trends of the series were almost identical but the absolute levels were slightly different. Afterwards the inclusion of further years of data did not lead to the same patterns only the last years is revised with a tendency to underestimate SSB and over-estimate F over the most recent years. The revision upwards of the SSB and downward of F is especially marked with the inclusion of 2013 year data. In recent assessments a marked retrospective pattern was observed for recruitment in 2008 with sharp increase in recruitment as more years were added to the assessment. This year, the inclusion of 2014 data has not produced the same patterns and the estimate of the recruitment in 2008 has slightly increased compared to last year estimate.

F2014 (average of F-at-length over lengths $15-80 \mathrm{~cm}$ ) was estimated at 0.34 and SSB at 203296 t.

Summary results from SS3 are given in Table 9.5 and Figure 9.9.

### 9.2.8 Historic trends in biomass, fishing mortality and recruitment

For recruitment, fluctuations appear to be without substantial trend over the whole series. The recruitment in 2008 was the highest in the whole series 700 millions of individuals and in 2014 decreased below mean level ( 240 million).

From high levels at the start of the series (100 000 t in 1980), the SSB has decreased steadily to a low level at the end of the 90s (25 000 t in 1998). Since that year, SSB has increased to the highest value of the series in 2012 (218 000 t ) and decreased slightly in 2013.

The fishing mortality is calculated as the average annual F for sizes $15-80 \mathrm{~cm}$. This measure of $F$ is nearly identical to the average $F$ for ages $1-5$. Values of $F$ increased from values around 0.5-0.6 in the late 70s and early 80s to values around 1.0 during the 90s. They declined sharply afterwards to 0.31 in 2012 and increased up to 0.34 in 2013.

### 9.3 Catch options and prognosis

### 9.3.1 Short - Term projection

For the current projection, unscaled $F$ is used, corresponding to $F(15-80 \mathrm{~cm})=0.33$.
The recruitment used for projections in this WG is the GM calculated from 1978 to the final assessment year minus 2.
Landings in 2016 and SSB in 2017 predicted for various levels of fishing mortality in 2016 are given in Table 9.6 and Figure 9.10. Maintaining status quo F in 2016 is expected to result in an increase in landings with respect to 2015 and a decrease in SSB in 2017 with respect to 2016.

### 9.3.2 Yield and biomass per recruit analysis

Options for long term projection are indicated in the Stock Annex.

Results of equilibrium yield and SSB per recruit are presented in Table 9.7 and Figure 9.11. The F-multiplier in Table 9.7 is with respect to status quo $F$ (average $F$ in the final 3 assessment years, 2012-2014). Considering the yield and SSB per recruit curves, $\mathrm{F}_{\text {max, }}$ $\mathrm{F}_{0.1}, \mathrm{~F}_{35 \%}$ and $\mathrm{F}_{30} \%$ are respectively estimated to be $84 \%, 57 \%, 62 \%$ and $72 \%$ of status quo F. The maximum equilibrium yield per recruit is around $1 \%$ above the equilibrium yield at $\mathrm{Fsq}_{\text {s }}$.

### 9.4 Biological reference points

Biological reference points for the stock of Northern Hake were calculated in 2014 (ICES 2014c) assessment working group and they are still considered valid.

|  | Type | Value | Technical basis |
| :--- | :--- | :--- | :--- |
| MSY | MSY Btrigger | 46200 | Bpa |
| Approach | FMSY | 0.27 | Fmsy in the combined stock <br> recruitment relationship (ICES <br> 2014c) |
|  | Blim | 33000 | SSB2006 Low level of SSB <br> followed by a sharp increase, <br> lower level of SSB would led to <br> lower recruitment level. |
| Precautionary | Bpa | 46 200 | 1.4Blim |
| Approach | Flim | Not defined |  |
|  | Fpa | Not defined |  |

### 9.5 Comments on the assessment

The retrospective pattern in 2008 recruitment was somewhat corrected in last benchmark (ICES, 2014a) but it worsen again in the following assessment working group when 2013 data was included (ICES, 2014). However, the inclusion of 2014 data has had very slight impact in the revision upwards of 2008 year recruitment and the increase in the SSB in the final part of the assessment was smaller than in previous years. During the last benchmark assessment the retrospective pattern was related with the length frequency distributions of the fleets and the way they are modelled. The model tried to explain the length frequency distributions observed through an increase in the recruitment. This was partially solved giving more flexibility to the selectivity and retention curves over time. As this pattern has not disappeared, in the future, more work will be needed to understand what is driving such a retrospective pattern. The discards of non-Spanish trawlers in VII and VIII have increased significantly in the last year. Their length frequency distribution has been made available in intercatch in the last two years, so it could be advisable to include them in the model. This year, the inclusion in the assessment of annual Scottish discard length frequency distribution of in others fleet has been tested. The impact in the results of the assessment was limited. However the fit to the length frequency distribution was not very good and the working group decided not to include this data in the assessment. However, the working group notes that in the current assessment the fit to the discard data of others fleet is done without any length frequency distribution data since 2008. As the Scottish data is considered representative of this discard of this fleet the working group will investigate in the future assessment the inclusion of this data into the assessment.

2014 length frequency distribution data of some fleets showed a very strange pattern. A preliminary analysis seems to indicate that this could be related to the way intercatch
does the allocations and the raising. Due to lack of time it was not possible to carry out an exhaustive analysis of the problem but it is considered crucial to identify the problem before next year assessment.

### 9.6 Management considerations

After several years of increasing trend in SSB, it decreased in 2013 and maintained almost constant in 2014. The fishing mortality increased slightly in 2014. The decrease in SSB is the consequence of high fishing mortality and low recruitments in 2009-2011. However, 2012 year class was the stronger in the series and will contribute to the SSB in the short term. It must be noted that the fast growth rate estimated by the model combined with the assumed high natural mortality rate ( $M=0.4$ since the 2010 benchmark) generates a rapid turn-over of the hake stock dynamic. This means that short term predictions in SSB and landings are strongly related to variations in recruitment. The short-term forecasts of SSB and yield obtained this year are influenced by the high recruitments estimated for 2012-2013.

## 10 Southern Stock of Hake

### 10.1 General

The type of assessment is "update" based on a previous benchmark assessment (WKSOUTH, 2014).

Data revisions:
Unallocated landings for 2013
Portuguese discard for 2012 and 2013.

### 10.1.1 Fishery description

Fishery description is available in the Stock Annex.
10.1.2 ICES advice for 2015 and Management applicable to 2014 and 2015.

## ICES Advice for 2015

ICES advises on the basis of the MSY approach that catches should be no more than 8417 tonnes in 2015. If discard rates do not change from the average of the years 20112013, this implies landings of no more than 7302 tonnes.

## Management Applicable for 2014 and 2015

Hake is managed by TAC, effort control and technical measures. The agreed TAC for Southern Hake in 2014 was 16266 t and in 2015 is 13826 t.

A Recovery Plan for southern hake was enacted in 2006 (CE 2166/2005). This plan aims to rebuild the stock to within safe biological limits by decreasing fishing mortality a maximum of $10 \%$ at year with a TAC constrain of $15 \%$. SSB target ( 35000 t ) is no longer considered suitable under the new assessment model. This regulation includes effort management limiting days at sea that is updated every year Reg. EU Council 104/2015 (annex II-b). The effort from fishing trips which retain $<8 \%$ hake are excluded from the regulation.

Technical measures applied to this stock include: (i) minimum landing size of 27 cm , (ii) protected areas, and (iii) minimum mesh size. These measures are set depending on areas and gears by several national regulations.
According to the Spanish Regulations AAA/1307/2013 the Spanish quota is shared by individual vessels The Portuguese regulations also established a closure for trawling off the southwest coast of Portugal between December and February.

### 10.2 Data

### 10.2.1 Commercial Catch: landings and discards

## Catches: landings and discards

Southern Hake catches by country and gear for the period 1972-last year, as estimated by the WG, are given in Table 10.1. Since 2011, estimates of unallocated landings have been included in the assessment. The method to estimate these landings has changed in 2013. A review of 2011 and 2012 estimates was performed to check the consistency of the new method and to correct these figures if necessary. Although the new method
provided reasonable figures for most species, this is not the case for Southern hake with landings well below those previously estimated (WD-3). The new figures were considered unrealistic and were rejected. This also raises the concern about the possible underestimation of landings for 2013 and 2014. It was not possible to suggest a reasonable correction since other factors partially explain the decrease of landings in 2013 and 2014. These factors are the increase of Spanish discards in 2013 and 2014 (see table 10.1) and also the decrease of survey abundance (SpGFS-WIBTS-Q4) in 2013 and 2014 (see Table 10.4). The group finally accepted 2013 and 2014 landing estimates because they are considered the best available information at the moment. WGBIE would welcome any further research to confirm the validity of these landing estimates.

In 2014, Portuguese landings were 2347 t, slightly below those from 2013 (2 744 t). Spanish official landings were 7154 t in 2013 and 7256 t in 2014. Unallocated landings were 1455 t in 2013 and 2246 t in 2014. Total landings in 2013 were 11661 t and 12011 t in 2014 well below TACs that were 14144 t in 2013 and 16266 t in 2014 Total discards in 2013 were 2553 t and 2602 in 2014. Total catches were 14214 and 14614 in 2013 and 2014.

Length distribution for 2014 landings and discards are presented in Tab 10.2. A slight change in mean size can be observed for landings (from 35.5 cm in 2013 to 33.8 in 2014) and discards (from 20.6 to 21.9) and catch from 27 to 27.9 cm .

## Growth, Length-weight relationship and $M$

An international length-weight relationship for the whole period ( $a=0.00659$; $\mathrm{b}=3.01721$ ) has been used since 1999. The assessment model follows a constant von Bertalanffy model with fixed Linf $=130 \mathrm{~cm}, \mathrm{t}_{\mathrm{o}}=0$ and estimating k parameter. Natural mortality was assumed to be 0.4 year $^{-1}$ for all ages and years.

## Maturity ogive

The stock is assessed with annual maturity ogives for males and females together. The maturity proportion in this assessment year is shown in Figure 10.2. L50 have oscillated from 31.5 cm in 2012 to 36.5 cm in 2013 and 31.7 cm in 2014. Mean historical figures were around 36 cm .

### 10.2.2 Abundance indices from surveys

Biomass, abundance and recruitment indices for the Portuguese and Spanish surveys respectively are presented in Table 10.3 and Table10.4 and Figure 10.3. The Spanish (SpGFS-WIBTS-Q4 and SPGFS-caut-WIBTS-Q4) and the Portuguese (PtGFS-WIBTSQ4) surveys are used to tune the model, by fitting the model estimates to the observed length proportions and survey trends.

The Portuguese Autumn survey (PtGFS-WIBTS-Q4) showed variable abundance indices with a minimum in 1993 and maximum in 2010. The survey was not performed in 2012. There were very high values in recent years. However the last figure is around the historical mean. The Spanish groundfish survey (SpGFS-WIBTS-Q4) shows low values for biomass and abundance in the early 2000s. These values increased from 2004 peaking to a historical maximum in 2009, after which they remained relatively stable until 2012. In 2013 and 2014 there was a further decrease to below the historical mean.

The recruitment indices of the SpGFS-WIBTS-Q4, SPGFS-caut-WIBTS-Q4 and PtGFS-WIBTS-Q4 (Figure 10.3) were highly variable in the past, showing good recruitments in recent years. In 2013, PtGFS-WIBTS-Q4 and SPGFS-caut-WIBTS-Q4 were both at the
respective maxima, while SpGFS-WIBTS-Q4 was slightly below the mean. In 2014 the 3 surveys decreased below historical means.

## Commercial catch-effort data

Effort and respective landings series are collected from Portuguese log-books maintained in DGRM and compiled by IPMA. For the Portuguese fleets, until 2011 most log-books were filled in paper but have thereafter been progressively replaced by elogbooks. In 2014 more than $90 \%$ of the log-books are being completed in the electronic version. The standardized CPUE from the Portuguese bottom-trawl fleet targeting roundfish is calculated by fitting a GLM to log-book data on landings and effort (modulated by additional fleet and catch characteristics), following the methods described in the stock annex and accepted by WKROUND (2010). The latest series (WD-5) is based on a renewed extraction of the complete logbook dataset housed in the DGRM (Portuguese administration) databases, which now includes both paper and e-logbooks. Following the application of the method, which now includes a greater number of vessels, the series was compared to the previously calculated series, showing similar trends (WD-5) although a different magnitude in numbers. The late availability of the 2014 data however meant that the new series was not yet incorporated in the assessment model.

Spanish sales notes and Owners Associations data were compiled by IEO to estimate fleet effort until 2012 and are presented in figure 10.4 and table 10.5. Spanish LPUE (SPCORUTR) estimates for 2013 and 2014 were estimated with a different methodology (for both landings and effort) and were not used in the model. WD-4 provided a review of LPUE in recent years with the new methodology. Effort increases between 10 and $20 \%$ and the landings up to $37 \%$. The length distribution provided only included 4 years of data. As soon as a more complete time series is available the data will be considered again to calibrate the model as a new time series.

The assessment model does not incorporate any additional LPUE as compared to 2013. The two fleets included in the assessment model are SP-CORUTR (from 1985 to 2012) and P-TR (from 1989 to 2010).

### 10.3 Assessment

The assessment carried out used the gadget model (length-age based) as decided by WKSOUTH (ICES, 2014) and described on the stock annex.

### 10.3.1 Model diagnostics

Likelihood profiles for each parameter estimated by the model are presented in Figure 10.5. This analysis is carried out in each parameter individually and it does not guarantee that the model finds an absolute minimum. It allows checking that the minimization algorithm found a minimum. The values on the horizontal axes of the plots represent multiplicative factors with respect to the estimated parameter value. To check for convergence the minimum likelihood value must correspond to the estimated parameter value (i.e. the multiplier 1). The change in likelihood may be very large if the model gives "understocking", i.e. if it is not able to produce enough fish to subtract the observed catches from the modelled population. Due to the distinct impact each parameter has on the likelihood value, the plots are presented scaled and unscaled. In Figure 10.5, all parameter estimates correspond to the minimum of the likelihood.

Residuals for surveys and abundance indices (SpGFS-WIBTS-Q4 and PtGFS-WIBTSQ4) and commercial fleets (SP-CORUTR and P-TR) are presented in Fig 10.6a-b, grouped in 15 cm classes (from 4 to 49 cm in surveys and 25 to 70 cm in commercial fleets). Most residuals are within the range of -1 to 1 ( $\pm 1$ s.d.). Surveys' residuals show a random distribution with the exception of PtGFS-WIBTS-Q4 for lengths $4-19 \mathrm{~cm}$, that shows figures above the model estimates in the last 5 years.
Regarding commercial fleets, P-TR was not available from 2011 to 2014 and SPCORUTR for the last two years (2013-14). P-TR ( $25-40 \mathrm{~cm}$ ) shows negative residuals with a downwards trend from 2005 to 2010. The difficulty of these indices to follow the abundance generated by the recent increase in recruitment may be due to the fact that discards are not included in the computation. Apart from this, the fits for these 3 length groups are quite consistent. The SP-CORUTR shows also quite consistent random residuals with the exception of the length group $55-70 \mathrm{~cm}$, which shows positive residuals for the last 6 years (2007-2012).

Figures 10.6 (c-i) present bubble plots of residuals for proportions at length. These proportions are grouped in 2 cm classes for all "fleets" used in the model calibration (see Stock Annex for descriptions). The model fits these proportions at length assuming a constant selection pattern for every "fleet" in the years and quarters in which length distributions are observed. The quality of the fit is different for different data sets, but not all of them contribute equally to the overall model fit. Projections are based on the selection patterns estimated only for landings ( $10.6-\mathrm{d}$ ) and discards ( $10.6-\mathrm{f}$ ). The residual analysis shows that there is an underestimation (positive residuals) in the most exploited lengths and overestimation on the larger sizes (negative residuals). Such patterns are not of major concern since the residuals' values are quite small (maximum $\sim 0.3$ ). The model takes into account the data precision when weighting the individual likelihood components (defined in the Stock Annex), so data sets with larger model residuals will have less impact on the overall model fit.

### 10.3.2 Assessment results

## Estimated parameters

The model estimates selection parameters for each "fleet" for which length proportions are fitted. Furthermore it estimates the von Bertalanffy growth parameter k. Results are presented in Figure 10.7. The selection patterns of different "fleets" of catches (catches in 1982-93; landings in 1994-latest; discards 1992-latest and Cadiz landings (1982-2004) are presented in the upper plot. The pattern corresponding to catches during 1982-93 shows higher relative efficiency for smaller fish (when compared with catches from 1994 onwards), which is in agreement with our assumption that before 1992 (when the minimum landing size was implemented) the importance of discards was relatively lower. The discards (1992-latest) and landings (1994-latest) selection patterns are used for projections.
Survey selection patterns are presented in the lower selection pattern panel. The Portuguese survey PtGFS-WIBTS-Q4 catches relatively larger fish than the Spanish surveys (SpGFS-WIBTS-Q4 and SPGFS-caut-WIBTS-Q4). Both Spanish surveys show a similar pattern. They are both performed with the same vessel and gear in every year, but since 2013 a new vessel has been used (without a significant impact in hake abundance estimates).
The von Bertalanffy k parameter was estimated to be 0.164 , the same as in the previous assessment.

## Historic trends in biomass, fishing mortality, yield and recruitment

Model estimates of abundance at length in the beginning of the $4^{\text {th }}$ quarter are presented in Figure 10.8. The figure shows a general increase of small fish in 2005-09, that contributes to an increase of large fish in more recent years.

Table 10.6 and Figure 10.9 present summary results with estimated annual values for fishing mortality (averaged over ages 1-3), recruitment (age 0 ) and SSB, as well as observed landings and discards.

Recruitment (age 0 ) is highly variable and presents three different periods: one from 1982 to 2003 with mean figures around 70 million (ranging from 40 to 120 mill); another between 2005 and 2009 with mean figures of 121 mill; and a latter period around the historic mean ( 80 mill). In 2014 it was 61.68 mill. Fishing mortality increased from the beginning of the time series ( $\mathrm{F}=0.36$ in 1982) peaking in 1995-97 around 1.18; declining to 0.78 in 1999 and remaining relatively stable until 2009 ( $\mathrm{F}=1.01$ ). F then progressively decreased to reach 0.68 in 2014. The SSB was very high at the beginning of the time series with values around 40000 t , then decreased to a minimum of 5810 t in 1998 . Since then biomass has continuously increased, reaching 18840 in 2014.

## Retrospective pattern for SSB, fishing mortality, yield and recruitment

Figure 10.10 presents the results of the assessments performed using the retrospective data series from 2014-2009. There is a clear trend in the retrospective pattern for recruitment, F and SSB. Recruitment shows high variability, whereas both recruitment and SSB show a tendency to be overestimated, in contrast to F which shows a tendency to be underestimated. The correction in 2014 is stronger than in previous years.

### 10.4 Catch options and prognosis

### 10.4.1 Short-term projections

The methodology used this year was developed during the latest benchmark (WKSOUTH, 2014) and described in the Stock Annex. Short term projections are presented in Fig. 10.11 and Table 10.7. Note that mortality in GADGET is length based. This may cause some small changes in F (ages 1-3) if the relative contributions of different length on these ages change from year to year. That is because F (1-3) in 2014 is 0.68 and $F(1-3)$ in 2015 is 0.67 . Furthermore, F multipliers do not apply linearly , e.g. if Fmult is $1, \mathrm{~F}$ is 0.67 however if Fmult $=0.5 \mathrm{~F}$ is 0.32 (see table 10.7).

In 2015 the expected SSB is 18856 t . Fsq for the intermediate year (2015) is estimated as the average of the last 3 assessment years scaled to last year ( 0.67 ). Recruitment for 2014 was accepted. Recruitment used for projections in years 2015-16 was the geometric mean of 1989-2013 (80 205 thousand). During the intermediate year, 2015, the expected yield (landings) is 12980 t and the SSB at the end of the year is expected to be 17684 t.

Different F multipliers applied in 2016 provide management alternatives according to different scenarios. Under Fsq (Fmult=1), F would be 0.67 , the expected yield would be 12416 t and SSB in 2017 would be 17683 t . Decreasing F by $10 \%$ (F mult=0.9), F would be 0.60 , the yield and SSB, 11502 t and 19354 t , respectively. This is outside the $-15 \%$ TAC constraint of the recovery plan, which would result in a yield of 11752 t and a SSB of 18895 t . With the MSY approach (F=0.24), Fmult would be 0.38 , the yield 5566 t and SSB 30438 t .

### 10.4.2 Yield and biomass per recruit analysis

The F that produces maximum landings per recruit was estimated following the Stock Annex. This results in Fmax $=0.24$ and F0.1=0.17 (Figure 10.12).
The following table shows the expected figures for different reference Fs:

|  | F (1-3) | Yield/R | SSB/R |
| :--- | :--- | :--- | :--- |
| Fsq | 0.67 | 0.17 | 0.24 |
| Fmax | 0.24 | 0.24 | 0.97 |
| F0.1 | 0.17 | 0.23 | 1.30 |
| F35\%SPR | 0.2 | 0.23 | 1.13 |

### 10.5 Biological reference points

Fmax ( $\mathrm{F}=0.24$ ) is the Southern hake Fmsy proxy.
Blim $=9000 \mathrm{t}$ based on Bloss. The stock recruitment plot does not show any clear sign of reduced recruitment at low SSB (Fig 10.13). However we opted for a conservative approach rejecting the 4 lowest SSB values (see Fig. 13) which results in a Bloss figure around 9000 t .

All reference points, including MSY ranges, will be reconsidered by ICES next October.

## Reference points

|  | Type | Value | Technical basis |
| :--- | :--- | :--- | :--- |
| MSY | MSY Btrigger | Not defined. |  |
| approach | FMSY | 0.24 | Fmax (WGHMM, 2010). |
|  | Blim | 9000 t | Bloss (WGBIE, 2014) |
| Precautionary | Bpa | Not defined. |  |
| approach | Flim | Not defined. |  |
|  | Fpa | Not defined. |  |

### 10.6 Comments on the assessment

Landings in the last two years are uncertain and could be underestimated.
Updates of two indices (SP-CORUTR and P-TR) could not be included in the model. These 2 indices are important calibration information for large fish.

Given the lack of abundance indices for large fish at the beginning of the time series, the SSB estimates for this period may be considered with caution.

Recruitment was quite high in 2005-09, afterward which it returned to a value around the historic mean. Surveys indicate that the latest recruitment abundance $(<20 \mathrm{~cm})$ is below the historical mean. .

The retrospective pattern shows a trend to overestimate SSB and underestimate F. This pattern has been stronger in 2014.

### 10.7 Management considerations

Landings have historically been well above the TACs since 2004. However, for the latest two years (2013 and 2014), landings have been well bellow the advised TAC.

The objective of the recovery plan was to rebuild the stock within safe biological limits, meaning to reach an SSB of 35000 t by 2015 . Since the enforcement of the plan the stock historical perception has changed caused by a wrong perception of growth and the subsequent implementation of a length based model. The SSB of the recovery plan is therefore no longer valid. A Blim $=9000 t$ was proposed in 2014 (ICES, 2014) based on Bloss. SSB in years 2014 and 2015 are around 19000 t, suggesting that the stock is inside safe biological limits

F in 2014 continues to be above Fmax. The stock is therefore being overexploited.
The retrospective pattern shows overestimation of SSB and underestimation of F. This could result in an overestimation of SSB predictions. The impact on the advised TAC is relatively low since both processes balance each other.

## 11 Nephrops (Divisions VIII ab, FU 23-24)

Type of assessment: biennal assessment
Main changes from the last assessment (WGBIE2014):
No relevant.
Previously, some changes have occurred since the IBP Nephrops 2012:

- Methodology for discard derivation (probabilistic approach replaced the proportional one).
- Scientific time series provided by the survey LANGOLF included in the tuning data (although the survey was stopped in 2014).

ICES description
Functional Units

VIIIa,b
Bay of Biscay North, VIII a (FU 23)
Bay of Biscay South, VIII b (FU 24)

### 11.1 General

### 11.1.1 Ecosystem aspects

This section is detailed in Stock Annex.

### 11.1.2 Fishery description

The general features of the fishery are given in Stock Annex.

### 11.1.3 ICES Advice for 2015

For 2015 ICES based on approach for data-limited stocks, advised that landings should increase by no more than $14 \%$ (i.e. 3214 t).
11.1.4 Management applicable for 2014 and 2015

| Species: | Norway lobster <br> Nephrops norvegicus | Zone: | VIIIa, VIIIb, VIIId and VIIIe <br> (NEP/8ABDE.) |
| :--- | :--- | :--- | :--- |
| Spain | 234 |  |  |
| France | 3665 |  |  |
| Union | 3899 |  | Analytical TAC |
| TAC | 3899 |  |  |

The Nephrops fishery is managed by TAC [articles 3, 4, 5(2) of Regulation (EC) No 847/96] along with technical measures. The agreed TAC for 2015 was 389 t (the same as for 2013 and 2014) whereas the ICES recommendation was to reduce catch. In 2014, total nominal landings reached 2807 t .

For a long-time, a minimum landing size of 26 mm CL ( 8.5 cm total length) was adopted by the French producers' organisations (larger than the EU MLS set at 20 mm CL i.e. 7 cm total length). Since December 2005, a new French MLS regulation ( 9 cm total length) has been established. This change has already significantly impacted on the data used by the WG (see report WGHMM 2007).

A mesh change was implemented in 2000 and the minimum codend mesh size in the Bay of Biscay was 70 mm instead of the former 55 mm for Nephrops, which had replaced 50 mm mesh size in 1990-91. 100 mm mesh size is required in the Hake box. For 2006 and 2007, Nephrops trawlers were allowed to fish in the hake box with mesh size smaller than 100 mm once they have adopted a square mesh panel of 100 mm . This derogation was maintained onwards.

As annotated in the Official Journal of the European Union (p.4, art. 27): "In order to ensure sustainable exploitation of the hake and Norway lobster stock and to reduce discards, the use of the latest developments as regards selective gears should be permitted in ICES zones VIIIa, VIIIb and VIIId."

In agreement with this, the National French Committee of Fisheries (deliberations $39 / 2007,1 / 2008$ ) fixed the rules of trawling activities targeting Nephrops in the areas VIIIa, VIIIb applicable from the $1^{\text {st }}$ April 2008. All vessels catching more than 50 kg of Nephrops per day must use a selective device from at least one of the following: (1) a ventral panel of 60 mm square mesh; (2) a flexible grid or (3) a 80 mm codend mesh size. The majority of Nephrops directed vessels (Districts of South Brittany) chose the increase of the codend mesh size whereas the ventral squared panel was adopted by multi-purpose trawlers (mainly in harbours outside Brittany).

A licence system was adopted in 2004 and, since then, there has been a cap on the number of Nephrops trawlers operating in the Bay of Biscay of 250 (less than 200 in 2014). In the beginning of 2006, the French producers' organisations adopted new additional regulations such as monthly quotas which had some effects on fishing effort limitation.

### 11.2 Data

### 11.2.1 Commercial catches and discards

Total catches, landings and discards, of Nephrops in division VIIIa,b for the period 19602014 are given in Table 11.1.
Throughout the mid-60's, the French landings gradually increased to a peak value of 7 000 t in 1973-1974, then fluctuated between 4500 and 6000 t during the 80's and the mid-90's. An increase has been noticeable during the early 2000's. Landings remained stable between 2008 and 2009 ( 3030 t and 2987 t ) whereas they had decreased compared with previous years ( 3176 in 2007, 3447 t in 2006 and 3991 t in 2005). In 2010 and 2011, total landings increased ( 3398 t and 3559 t respectively). In 2012 and 2013, a strong reduction of the landings occurred ( 2520 t and 2380 t respectively). In 2014, landings increased significantly ( $2807 \mathrm{t}:+18 \%$ ). Landings since 2008 have been reached under the new selectivity regulations.
Males usually predominate in the landings (sex ratio, defined as number of females divided by total, fluctuates between 0.31 and 0.46 for the overall period 1987-2014) and in a lesser degree in the removals (sexio ratio in the range 0.35-0.49). Females are less accessible in winter because of burrowing and, also, they have a lower growth rate. The female proportion in landings slightly increased up to the late 1990's/early 2000's, but this trend was not confirmed in recent years probably because of the MLS increase (December 2005) and, moreover, because of the new selectivity regulations (April 2008).

Discards represent most of the catches of the smallest individuals as indicated by the available data (Figure 11.1). The average weight of discards per year in the period up
to early 2000's (not routinely sampled) is about 1550 t whereas discard estimates of the recent sampled years (2003-2014) reached a higher level of 1993 t . This change in the amount of discards could be due to the restriction of individual quotas (notably applied since 2006), the strength of some recruitments in the middle of 2000's and the change in the MLS (which tends to increase the discards), although the change in the selectivity should tend to reduce the discards. The relative contribution of each of these three factors remains unknown. In 2014, 118 million individuals were estimated to have been discarded (1326t).

### 11.2.2 Biological sampling

Discard data by sampling on board are available for 1987, 1991, 1998 and from 2003. For the intermediate years up to 2002, since the former WGNEPH, numbers discarded at length were derived by the "proportional method" calculating discards by sex for years with no sampling onboard by applying identical quarterly LFDs of the preceding sampled year raised to the quarterly landings i.e. for years 1992-1997 derivation used quarterly LFDs from 1991. This method was suspected to induce inter-dependence throughout the time series, therefore, lack of contrast for annual recruitment. IBP Nephrops 2012 even not finally conclusive investigated the probabilistic (logistic) approach developed for the WGHMM since 2007 (Table 11.2; see Stock Annex) and compared with the previous discard derivation. The probabilistic calculation provides wider variations on number of removals for age group 1 and 2 after conversion of the size composition to an age one (under assumptions involving in individual growth by sex according to Von Bertalanffy's function as used by previous WGs). Since the WGHMM 2012, the probabilistic method has been chosen: the derivation is performed by sex and quarter using logistic function describing the s-shaped hand-sorting onboard and assuming symmetrical densities of probability for yearly LFDs as tested on years with sampling onboard before MLS change (up to 2005).
Since 2003, discards have been estimated from sampling catch programmes on board Nephrops trawlers ( 488 trips and 1402 hauls have been sampled over 12 years). In spite of improvements in agreement between logbook declarations and auction hall sales since the middle of 2000's, the quality of crossed information fluctuates between years. e.g. for years 2007-2014 the percentage of cross-validation item by item between logbooks and sales was comprised in a wide range of 69 to $90 \%$ ( $85 \%$ for 2014). Therefore, the total number of trips is usually not well known and needs to be estimated under assumptions. This can be done using the number of auction hall sales, when boats conduct daily trips, which is the case in the northern part of the fishery, but not in the southern one. Discard sampling from the southern part of the fishery was carried out only once in the past (2005), but the sampling plan has been routinely applied since 2010.

The length distribution of landings, discards, catches and removals are presented in Tables 11.3.a-h and in Figure 11.1. Removals at length are obtained by adding the landings and "dead discards" and applying a discard mean survival rate of 30\% (Charuau et al., 1982). Combined sex mean lengths are presented for catches, landings and discards in Figure 11.2.

### 11.2.3 Abundance indices from surveys

For many years, abundance indices were not available for this stock. A survey specifically designed to evaluate abundance indices of Nephrops commenced in 2006 (with the most appropriate season: $2^{\text {nd }}$ quarter, hours of trawling: around dawn and dusk and fishing gear: twin trawl). This survey (called LANGOLF; see Stock Annex) occurred
once a year in May and its sampling design was stratified using sedimentary strata. Therefore, as regards the investigations carried out during the IBP Nephrops 2012, its results for abundance indices were included in the assessment (WGHMM 2012, 2013; WGBIE 2014). The time series provided by this survey was interrupted for financial reasons (the survey has not been conducted since May 2014). Otherwise, a new experimental survey combining UWTV burrows counting and trawling indices as routinely operated for many Nephrops stocks on areas VI and VII was initiated in September 2014. Trawling was operated by two commercial vessels applying the same sampling plan (stratified random) and using the same twin trawls ( 20 mm codend mesh size) as those of the former LANGOLF survey. The burrows counting was undertaken by the Irish scientific vessel "Celtic Voyager" on the basis of a systematic sampling plan with no stratification. Some preliminary geostatistical investigations were carried out (see WDs 7 and 8; WGBIE 2015). This survey should also be conducted in July 2015 which is a more adequate period accordingly to the female availability. The choice of survey dates is constrained by the schedule time for UWTV Irish equipment and staff.

### 11.2.4 Commercial catch-effort data.

## Commercial fleets used in the assessment to tune the model

Up to 1998, the majority of the vessels were not obliged to keep logbooks because of their size and fishing forms were established by inquiries. Since 1999, logbooks became compulsory for all vessels longer than 10 m . The available log-book data cannot be currently considered as representative for the fishing effort of the whole fishery during the overall time series. Hence, since 2004, it was attempted to define a better effort index.

Effort data indices, landings and LPUE for the "Le Guilvinec District" Nephrops trawlers in the $2^{\text {nd }}$ quarter (noted GV-Q2) are available for the overall time series (Table 11.4; Figure 11.3). Effort increased from 1987 to 1992, but there has been a decreasing trend since then. In 2012-2014, the lowest fishing effort for the whole period was observed. The downwards trend in effort can be explained by the decrease in the number of fishing vessels following the decommissioning schemes implemented by the EU. The LPUEs of the GV-Q2 fleet were reasonably stable for a long period, fluctuating around a long-term average of $13.1 \mathrm{~kg} /$ hour (Figure 11.3), with three pics values occurring in 1988, 2001 and 2010. LPUE increased steeply between 2009 and $2010(+35 \%$ : from 13.8 $\mathrm{kg} / \mathrm{h}$ to $18.6 \mathrm{~kg} / \mathrm{h}$ maximum of the historical series), then strongly decreased in 2011 ($19 \%$ : $15.1 \mathrm{~kg} / \mathrm{h})$, remained stable in $2012(15.2 \mathrm{~kg} / \mathrm{h})$ and steeply declined in $2013(-15 \%$ : $12.8 \mathrm{~kg} / \mathrm{h})$. In spite of the steep increase of the yearly landings between 2013 and 2014, the GV-Q2 LPUE index remained stable in $2014(12.7 \mathrm{~kg} / \mathrm{h})$.

Changes in fishing gear efficiency and individual catch capacities of vessels, imply that the time spent at sea may not be a good indicator of effective effort and hence LPUE trends are possibly biased. Since the early 90's, the number of boats using twin-trawls increased ( $10 \%$ in 1991, more than $90 \%$ in recent years, almost $100 \%$ in the northern part of the fishery) and also the number of vessels using rock-hopper gear on the rough sea bottom of the extreme NW part of the central mud bank of the Bay of Biscay. Moreover, an increase in onboard computer technology has occurred. The effects of these changes are difficult to quantify as twin-trawling is not always recorded explicitly in the fisheries statistics and improvement due to computing technology is not continuous for the overall time series.

### 11.3 Assessment

No analytical assessment was carried out in 2015. Updated data do not change the perception of the stock status from last year assessment.

### 11.4 Catch options and prognosis

No short-term projections and yield per recruit analysis were carried out.

### 11.5 Biological reference points

In previous analytical assessments, $\mathrm{F}_{\text {max }}$ was proposed as a satisfactory $\mathrm{F}_{\text {ms }}$ proxy for the stock although the rejection of the XSA assessment for this stock suggests to define new biological reference points based on the new survey combining UWTV and trawling (benchmark workshop proposed for the end of 2016).

### 11.6 Comments on the assessment

The continuation of the French Nephrops trawlers onboard sampling programme will avoid the use of "derived" data for missing years (13 years on 28). Since 2009, there has been a improvement of the sampling design as many trips were sampled in the Southern part of the fishery. Derivation based on probabilistic approach should improve diagnostic in further analytical investigations when new alternative assessment methods will be applied.

### 11.7 Information from the fishing industry

Many exchanges occurred between scientists and the fishing industry prior to the WG in the case of the partnership for the new UWTV/trawl combined survey (scientific methodological and financial supporting project). The industry underlined the heterogeneous feature of the whole area of the stock and commented on the application of only one tuning series involved in the northern part of the fishery and its extrapolation to the southern one. They emphasized the necessity of applying additional tuning commercial information on the southern part of fishery. They have been aware of the downwards trend for the stock between the late 2000's and the early 2010's, moreover they considered the unfavourable context induced by the interruption of the LANGOLF series and the necessity to routinely replace it by an UWTV one. For 2014, industry commented the contradictory result between the steep increase of the yearly landings and the stability of the LPUE seasonal indices from the commercial tuning fleet. They pointed out that the 2014's fishing profile does not correspond to the typically seasonal one for Nephrops because global indices were stronger in the $3^{\text {rd }}$ quarter of the year than in the $2^{\text {nd }}$ one.

### 11.8 Management considerations

Even with no quantitative analytical investigations the stability of the commercial LPUEs combined with the relative reduction of the discards suggest to not change the perception for the stock.

## 12 Nephrops in Division VIIIc

The ICES Division VIIIc includes two Nephrops Functional Units: FU 25, North Galicia and FU 31, Cantabrian Sea.

### 12.1 Nephrops FU 25 (North Galicia)

### 12.1.1 General

### 12.1.1.1 Ecosystem aspects

See Annex K

### 12.1.1.2 Fishery description

See Annex K
12.1.1.3 Summary of ICES Advice for 2015 and management applicable to 2015 and 2016

## ICES advice for 2015

The advice for these Nephrops stocks is biennial and valid for 2015 and 2016.
ICES advises on the basis of the precautionary considerations that there should be directed fishery and bycatch should be minimized.

To protect the stock in this Functional Unit, ICES advices that management area should be consistent with the assess area. Therefore, management should be implemented at the Functional Unit level.

## Management applicable to 2014 and 2015

A recovery plan for southern hake and Iberian Nephrops stocks has been in force since the end of January 2006. The aim of the recovery plan is to rebuild the stocks within 10 years, with a reduction of $10 \%$ in F relatively to the previous year and the TAC set accordingly (Council Regulation (EC) No. 2166/2005). TACs of 67 t and 60 t were set for the whole of Division VIIIc for 2014 and 2015, respectively.

### 12.1.2 Data

### 12.1.2.1 Commercial catches and discards

Up to 2010, in previous years landings have been estimated by the WG based on IEO scientific estimations. The information was compiled by IEO from sale sheets and Owners Associations where the Nephrops landings allocation was carried out based on landing port criteria. Since 2011, the Spanish Authority for Fisheries (Secretaría General de Pesca, SGP) who is also the National Authority for the Data Collection Framework established a new policy and general approach in the provision of official data on catches and fishing effort. So, since 2011 Nephrops landings are official landings.

Unlike the IEO scientific estimates, official landings are derived from logbooks. This source of information allows the landings disaggregation by ICES statistical rectangles. In WGHMM 2013 was noticed that some Nephrops catches were recorded into statistical rectangles outside of the FU 31 definition. In 2012 and 2013 Nephrops catches recorded into statistical rectangles outside of this FU were considered as part of the landings in FU 25. In 2014 Spanish landings of Nephrops have been uploaded to InterCatch broken
down by ICES statistical rectangle for first time according to the 2014 ICES Data Call requirements. However, only were uploaded to Intercatch $83.7 \%$ of 2014 landings which were recorded inside ICES statistical rectangles defined as FU 31 (WD № 3, Castro). As the outer rectangles were not defined in InterCatch, the remaining landings couldn't be upload this year but this will be for next year WG.

Landings were reported only by Spain. Since the early 90s landings declined from about $400 t$ to less than $100 t$ in 2003. In the period 2004-2014, landings show a continuous decreasing trend up to 9 t in the last year (Table 12.1.1). The time series of the commercial landings (Figure 12.1.1) shows a clear declining trend, with present values representing approximately less than $1 \%$ of the landings in the 70 s. Information on discards was sent to the WG through InterCatch. There are no discards in this functional unit.

### 12.1.2.2 Biological sampling

Length frequencies by sex of the Nephrops landings are collected as a rule on a monthly basis. The sampling levels are showed in Table 1.3.

Annual length compositions for males and females combined, mean size and mean weight in the landings are given in Table 12.1.2 for the period 1981-2014 (see also Figures 12.1.2a and 12.1.2b).

Mean sizes in the landings shows an increasing trend in the time series in both sexes. The maximum value was recorder in 2009, reaching 48.5 and 45.1 mm CL for males and females, respectively. However, decreasing trend was observed from 2010 to 2014 (Figure 12.1.1). In 2014, the mean size in females was 39.2 mm of carapace length while 40.2 mm for males.

### 12.1.2.3 Commercial catch-effort data

Fishing effort and LPUE data were available for the A Coruña trawl fleet (SPCORUTR8c) from 1986 (Table 12.1.3 and Figure 12.1.1). The method to estimate the effort has changed since 2009. Before this date the effort series (SP-CORUTR8c) was estimated using a different fleet segmentation. Since implementation of the current DCF sampling program (EC, 2008), the Northwester Spanish OTB fleet was split into two different metiers: OTB_DEF_>55_0_0 (trips targeting demersal fish that include Nephrops) and OTB_MPD_>55_0_0 (trips targeting pelagic fish accompanied by demersal fish). In this WG are presented a revision of the 2009-2014 effort and LPUE series in FU 25 using only the demersal métier OTB_DEF_>55_0_0 and they have been renamed this year as SP-LCGOTBDEF (WD № 4, Castro \& Morlan). As a consequence it must be noted that the method uses to calculate the LPUE of SP-LCGOTBDEF is not consistent across the period as shown in Figure 12.1.1.

The available time series of effort (Figure 12.1.1) shows a continuous decreasing trend. The lowest effort was observed in 2011, representing approximately $15 \%$ of fishing effort in the 70's. In 2012-2014 period, effort increased slightly but it remains at very low level. Effort of the bottom trawl in this fishery is directed primarily at a set of demersal and bottom species, with Nephrops making only a small contribution to the whole landings.

The overall trend of LPUE is declining too (Figure 12.1.1). After a period quite variable at the beginning of the time series, LPUE remained relatively stable at around 40 $\mathrm{kg} /$ trip between 1993 and 1997. Since then, LPUE has fluctuated at low levels but shows a decreasing trend up to 2014, the lowest value recorded in the time series $(4.5 \mathrm{Kg} /$ trip $)$.

### 12.1.3 Assessment

As the perception of the stock did not change from previous year, no update of the assessment was performed.

### 12.1.4 Biological reference points

There are not reference points defined for this stock.

### 12.1.5 Management Considerations

Nephrops is taken as by catch in the mixed bottom fishery. The overall trend in landings of Nephrops from the North Galicia (FU25) is strongly declining. Landings have dramatically decreased since the beginning of the series (1975-2014), representing less $1 \%$ of the landings.
A recovery plan for southern hake and Atlantic Iberian Nephrops stocks was approved in December 2005 (Council Regulation (EC) No 2166/2005) and implemented since January 2006. The management objective is to rebuild the stock to safe biological limits within a period of 10 years. This recovery plan includes a procedure for setting the TACs for Nephrops stocks, complemented by a system of fishing effort limitation (a reduction of $10 \%$ in the fishing mortality rate in the year of its application as compared with the fishing mortality rate estimated for the preceding year, within the limits of $\pm 15 \%$ of the preceding year TAC).

### 12.2.1.2 Fishery description

See Annex K
12.2.1.3 Summary of ICES Advice for 2015 and management applicable to 2015 and 2016

## ICES advice for 2015

The advice for these Nephrops stocks is biennial and valid for 2015 and 2016.
ICES advises on the basis of the precautionary considerations that there should be directed fishery and bycatch should be minimized.

To protect the stock in this Functional Unit, ICES advices that management area should be consistent with the assess area. Therefore, management should be implemented at the Functional Unit level.

## Management applicable to 2014 and 2015

TACs of 67 and $60 t$ were set for the whole of Division VIIIc for 2014 and 2015, respectively. A fishing effort limitation is also applicable in accordance with the southern hake and Nephrops recovery plan.

### 12.2.2 Data

### 12.2.2.1 Commercial catches and discards

Up to 2010, landings have been estimated by the WG based on IEO scientific estimations. The information was compiled by IEO from sale sheets and Owners Associations where the Nephrops landings allocation was carried out based on landing port criteria. Since 2011, the Spanish Authority for Fisheries (Secretaría General de Pesca, SGP) who is also the National Authority for the Data Collection Framework established a new policy and general approach in the provision of official data on catches and fishing effort. So, since 2011 Nephrops landings are official landings.

Unlike the IEO scientific estimates, official landings are derived from logbooks. This source of information allows the landings disaggregation by ICES statistical rectangles. In WGHMM 2013 was noticed that some Nephrops catches were recorded into statistical rectangles outside of the FU 31 definition. In 2012 and 2013Nephrops catches recorded into statistical rectangles outside of this FU were considered as part of the landings in FU 31. In 2014 Spanish landings of Nephrops have been uploaded to InterCatch broken down by ICES statistical rectangle for first time according to the 2014 ICES Data Call requirements. However, only were uploaded to InterCatch $77.4 \%$ of 2014 landings which were recorded inside ICES statistical rectangles defined as FU 31 (WD № 3 Castro). As the outer rectangles were not defined in InterCatch, the remaining landings couldn't be upload this year but this will be for next year WG.

Nephrops landings from FU 31 are reported by Spain (the only participant in the fishery) (Table 12.2.1 and Figure 12.2.1) and are available for the period 1983-2014. The highest
landings were recorded in 1989 and 1990, with 177 t and 174 t , respectively. Since 1996 landings have declined sharply from 129 t to less than 4 t in 2014.

### 12.2.2.2 Biological sampling

Length frequencies by sex of Nephrops landings were collected by the biological sampling programme. The sampling levels are shown in Table 1.3.

Mean size of males and females in the landings fluctuated during 1988-2014 (Figure 12.2.1). Data show a general increasing trend for both sexes to 2009 (Figure 12.2.1), where it was recorded the highest values (males with 55.8 mm and females with 45.9 mm CL). In 2011 the mean carapace length decreased slightly in relation to the previous year, and it has fluctuated onwards although with an increasing trend. Mean size in 2014 was around 52.0 and 46.8 mm of carapace length in males and females, respectively.

### 12.2.2.3 Commercial catch-effort data

The fishing effort and LPUE data series includes three bottom trawl fleets operating in the Cantabrian Sea with home harbors in Avilés, Santander and Gijón. In last years, the information of the different fleets is intermittent, although Santander data series is the largest (up to 2013). A new effort series including the Santander, Avilés and Gijón effort together from 2009 to 2014 are presented in this WG. In order to standardize the effort units in Division VIIIc, the new effort series is expressed in trips. The series of effort for Santander, Avilés and Gijón will be combined for the years prior to 2009 for the next WG.

The available old time series of effort shows a period of relative stability from the early 1980s to the beginning of the 1990s. Since 1992, effort shows a marked downward trend (Figure 12.2.1) with the lowest value recorded in 2005 ( 364 fishing days corresponding to Santander fleet). The increase in the use of other gears (HVO and pair trawl) resulted in the reduction in effort by the baca trawl fleet, the only gear fishing for Nephrops. After a slight increase in 2006 and 2007, fishing effort declined again and it has remained at low levels in the last five years. The new effort series (Santander+Avilés+Gijón) from 2009 to 2014 (expressed in trips) shows an increasing trend since 2010, ranging between 850 trips to 1083 trips (Figure 11.2.1). The Santander LPUE series shows fluctuations around the general downward trend (Figure 12.2.1). The LPUE reached the lowest value of the time series in 2013 ( $2.3 \mathrm{Kg} /$ fishing days), last available data. The new LPUE series (Santander+Avilés+Gijón) shows a decreasing trend in the time series suggesting a very low Nephrops abundance in FU 31.

### 12.2.3 Assessment

As the perception of the stock did not change from previous year, no update of the assessment was performed.

### 12.2.4 Management considerations

Nephrops is taken as by catch in the mixed bottom fishery. The overall trend in landings of Nephrops from the Cantabrian Sea strongly declining. Landings have dramatically decreased since the beginning of the series (1982-2014), representing less $1 \%$ of the landings.

A recovery plan for southern hake and Atlantic Iberian Nephrops stocks including a fishing effort reduction was implemented and enforced in 2006.

Table 12.2.1. Nephrops FU31, Cantabrian Sea. Landings in tonnes.

Figure 12.2.2. Nephrops FU31, Cantabrian Sea. Long-term trends in landings, effort, LPUE and mean sizes.

### 12.3 Summary for Division VIIIc

Nephrops in Division VIIIc includes two FUs (North Galicia, FU 25 and Cantabrian Sea, FU 31). Table 12.3.1 shows the landings in Division VIIIc. Landings from both FUs have declined dramatically. Landings in Division VIIIc were below the TAC in recent years, and therefore the TAC has not been restrictive.

The very low levels of landings from FU 25 and FU 31 and the decreasing LPUE trends to 2014 indicate that both stocks are in very poor condition.

A recovery plan for southern hake and Atlantic Iberian Nephrops stocks was approved in December 2005 (Council Regulation (EC) No 2166/2005) and implemented since January 2006. This recovery plan includes a procedure for setting the TACs for Nephrops stocks, complemented by a system of fishing effort limitation (a reduction of $10 \%$ in the fishing mortality rate in the year of its application as compared with the fishing mortality rate estimated for the preceding year, within the limits of $\pm 15 \%$ of the preceding year TAC). ICES has not evaluated the recovery plan.

Table 12.3.1. Nephrops in Division VIIIc. Landings by FU (tonnes).

| Year | FU 25 | FU 31 | Unallocated | DIVISION VIIIC |
| :---: | :---: | :---: | :---: | :---: |

## 13 Nephrops in Division IXa

The ICES Division IXa has five Nephrops Functional Units: FU 26, West Galicia; FU 27 North Portugal; FU 28, Alentejo, Southwest Portugal; FU 29, Algarve, South Portugal and FU 30, Gulf of Cádiz.

### 13.1 Nephrops FU 26-27, West Galicia and North Portugal (Division IXa)

### 13.1.1 General

### 13.1.1.1 Ecosystem aspects

See Annex L

### 13.1.1.2 Fishery description

See Annex L
13.1.2 Summary of ICES Advice for 2015 and management applicable to 2015 and 2016

ICES advice for 2015
The advice for these Nephrops stocks is biennial and valid for 2015 and 2016.
ICES advises on the basis of the precautionary considerations that there should be no directed fishery and bycatch should be minimized.

To protect the stock in this Functional Unit, ICES advices that management area should be consistent with the assess area. Therefore, management should be implemented at the Functional Unit level.

## Management applicable to 2014 and 2015

A recovery plan for southern hake and Iberian Nephrops stocks has been in force since the end of January 2006. The aim of the recovery plan is to rebuild the stocks within 10 years, with a reduction of $10 \%$ in F relative to the previous year and the TAC set accordingly (Council Regulation (EC) No. 2166/2005).

In order to reduce F on Nephrops stocks in this Division even further, a seasonal ban was introduced in the trawl and creel fishery for two boxes, located in FU 26 and 28, in the peak of the Nephrops fishing season. These boxes are closed for Nephrops fishing in June-August and in May-August, respectively.

ICES has not evaluated the current recovery plan for Nephrops in relation to the precautionary approach.

The TAC set for the whole Division IXa was 221 t for 2014 and 254 t for 2015, respectively, of which no more than $6 \%$ may be taken in FUs 26 and 27. The maximum number of fishing days per vessel was fixed at 127 and 114 days for Spanish vessels and at 126 and 113 days for Portuguese vessels for these two years (Annex IIb of Council Regulations nos. 43/2014 and 104/2015). The number of fishing days included in these regulations is not applicable to the Gulf of Cadiz (FU 30), which has a different regime.

### 13.1.3 Data

### 13.1.3.1 Commercial catches and discards

Up to 2010, landings have been estimated by the WG based on IEO scientific estimations. The information was compiled by IEO from sale sheets and Owners Associations where the Nephrops landings allocation was carried out based on landing port criteria. Since 2011, the Spanish Authority for Fisheries (Secretaría General de Pesca, SGP) who is also the National Authority for the Data Collection Framework established a new policy and general approach in the provision of official data on catches and fishing effort. So, since 2011 Nephrops landings are the official landings.

Unlike the IEO scientific estimates, official landings are derived from logbooks. This source of information allows the landings disaggregation by ICES statistical rectangles. In WGHMM 2013 it was noticed that some Nephrops catches were recorded into statistical rectangles outside of the FU 26-27 definition. In 2012 and 2013 Nephrops catches from statistical rectangles outside of this FU were considered as part of the landings in FU 26-27. In 2014 Spanish landings of Nephrops have been uploaded to Intercatch broken down by ICES statistical rectangle for the first time according to the 2014 ICES Data Call requirements. However, only the landings recorded inside ICES statistical rectangles defined as FU 26-27 were uploaded to InterCatch, which correspond to $96.3 \%$ of 2014 landings (WD № 3, Castro). As the outer rectangles were not defined in Intercatch, the remaining landings couldn't be upload this year but this should be done for next year WG.

Landings in these FUs are reported by Spain and minor quantities by Portugal. The catches are taken by the Spanish fleets fishing on the West Galicia (FU 26) and North Portugal (FU 27) fishing grounds, and by the Portuguese fleet fishing on FU 27. Nephrops represents a minor percentage in the composition of total trawl landings and can be considered as by-catch although it is a very valuable species.

Along the time series, landings by the Spanish fleets are mostly from FU 26, together with smaller quantities taken from FU 27. However, since 2011 landings are very low in both FUs. Prior to 1996, no distinction was made between the two FUs, and therefore they are considered together.

Two periods can be distinguished in the time series of landings available 1975-2014 (Figure 13.1.1). During 1975-1989, the mean landing was 680 t , fluctuating between 575 and 800 t approximately. Since 1990 onwards there has been a marked downward trend in landings, being below 50 t from 2005 to 2011..In the last three years, landings were minimal (less than 10). In 2014, landings were 4 t . Information on discards was sent to the WG through Intercatch although no discards are recorded in these FUs.

Total Portuguese landings from FU 27 have decreased from almost 100 t in 1988 to just 1 t in 2012, 2013 and 2014.

### 13.1.3.2 Biological sampling

Length frequencies by sex of the Nephrops landings are collected monthly. The sampling levels are shown in Table 1.3.

Mean size for both sexes shows an increasing trend from 2001 to 2010 with the highest value recorded in 2010 ( 52.0 mm CL in males and 43.7 mm CL in females) (Figure 13.1.1). In contrast, mean carapace length declined in both sexes in 2011-2013 period. The mean size in 2014 was 42.4 mm and 35.6 mm of carapace length in males and females, respectively. Annual length compositions for males and females combined,
mean size and mean weight in landings for the period 1988-2014 are given in Table 13.1.2 and Figure 13.1.2.

### 13.1.3.3 Commercial catch-effort data

Fishing effort and LPUE estimates are available for Marin trawl fleet (SP-MATR) for the period 1990-2014 (Table 13.1.3). The overall trend for the LPUE of SP-MATR is decreasing, with some stability in the 2007-2009 periods although at very low level ( $\sim 17.5$ $\mathrm{Kg} /$ trip $)$. From 2010 to 2014, LPUE downfall again to the lowest recorded in the time series ( $0.8 \mathrm{Kg} /$ trip) indicating that the Nephrops abundance is at very low level.

Time series of fishing effort and LPUE of the bottom trawl fleets with the Spanish home ports of Muros (1984-2003), Riveira, (1984-2004), and Vigo, (1995-2008 and 2010) are also available. These data are plotted in Figure 12.1.1 for complementary information.

### 13.1.4 Assessment

As the perception of the stock did not change from previous year, no update of the assessment was performed.

### 13.1.5 Biological reference points

There are not reference points defined for this stock.

### 13.1.6 Management Considerations

Nephrops is taken as by catch in a mixed bottom trawl fishery. Landings of Nephrops have substantially declined since 1995. Recent landings represent less than $1 \%$ of the average landings in the early period of the time series (1975-1992). Fishing effort in FU 26-27 has decreased throughout the time series.

A recovery plan for southern hake and Iberian Nephrops stocks was approved in December 2005 (CE 2166/2005) and implemented since January 2006.

The recovery plan includes a reduction of $10 \%$ in the hake F relative to the previous year and TAC set accordingly, within the limits of $\pm 15 \%$ of the previous year TAC (Council Regulation (EC) No 2166/2005). Although no clear targets were defined for Norway lobster stocks in the plan, the same $10 \%$ reduction has been applied to these stocks effort and TAC. The number of allowed fishing days is set in each year regulations (Council Regulations (EC) Nos. 51/2006, 41/2007, 40/2008, 43/2009, 53/2010, $57 / 2011,43 / 2012,39 / 2013,43 / 2014$ and $104 / 2015)$. The recovery plan target and rules have not been changed since it was implemented. This plan also includes a seasonal closure (June-August) for Nephrops in an area of the West Galicia (FU 26) fishing grounds, which was amended to the Council Regulation (EC) No 850/98.

See the Stock Annex (in Annex L of WG report)

### 13.2.1.2 Fishery description

See the Stock Annex (in Annex L of WG report)
13.2.1.3 ICES Advice and Management applicable for 2015 and 2016

## ICES Advice for 2015 and 2016

The advice for these stocks is biennial and valid for 2015 and 2016. Based on the ICES approach for data-limited stocks, ICES advises that catches in 2015 for FUs 28 and 29 should be no more than 226 tonnes.

To protect the stock in this Functional Unit, ICES advices that management area should be consistent with the assess area. Therefore, management should be implemented at the Functional Unit level.

## Management applicable for 2015 and 2016

A recovery plan for southern hake and Iberian Nephrops stocks has been in force since the end of January 2006. The aim of the recovery plan is to rebuild the stocks within 10 years, with a reduction of $10 \%$ in F relative to the previous year and the TAC set accordingly (Council Regulation (EC) No. 2166/2005).

In order to reduce F on Nephrops stocks in Division IXa even further, a seasonal ban was introduced in the trawl and creel fishery for two boxes (geographic areas) located in FU 26 and in FU 28, in the peak of the Nephrops fishing season. These boxes are closed for Nephrops fishing in June-August and in May-August, respectively.
ICES has not evaluated the current recovery plan for Nephrops in relation to the precautionary approach.

The TAC set for the whole Division IXa was 221 and 254 t for 2014 and 2015, respectively, of which no more than $6 \%$ may be taken in FUs 26 and 27. The maximum number of fishing days per vessel was fixed at 127 and 114 days for Spanish vessels and at 126 and 113 days for Portuguese vessels for these two years (Annex IIb of Council Regulations 43/2014 and 104/2015). The number of fishing days included in these regulations is not applicable to the Gulf of Cadiz (FU 30), which has a different effort management regime.

### 13.2.2 Data

### 13.2.2.1 Commercial catches and discards

Table 13.2.1 and Figure 13.2 .1 show the landings data series for these Functional Units (FUs). For the time period 1984 to 1992, the recorded landings from FUs 28 and 29 have fluctuated between 420 and 530 t , with a long-term average of about 480 t , falling drastically in the period 1990-1996, down to 132 t. From 1997 to 2005 landings have increased to levels observed during the early 1990s but decreased again in recent years.

The value landings in 2009-2011 was approximately at the same level ( $\approx 150 \mathrm{t}$ ), increasing to an average value of 220 t in the years 2012-2013. The landings in 2013 and 2014 decreased due to TAC limitations. In 2013 the fishery was closed in the last quarter whereas in 2014 it was closed in the period August to mid-November.

Since 2011, landings include the Spanish official landings. Spanish vessels are licensed for crustaceans in these FUs under a bilateral agreement since 2004. No data from these vessels' operation is available prior to 2011.

Spanish official landings are derived from logbooks. This source of information allows landings disaggregation by ICES statistical rectangles. In 2012 and 2013, Nephrops catches recorded in statistical rectangles outside the FUs in Division IXa were allocated to the closest rectangles in each FU. In 2014, $100 \%$ of the caches were into FU 28-29 definition (WD 03).

Males are the dominant component in all landings with exception for 1995 and 1996 when total female landings exceeded male landings (ICES, 2006). For the period 20022011 male to female sex-ratio has been close to 1.5:1. The years 2012 and 2013 present a ratio of 2.3:1. The sex-ratio in 2014 was close to 1:1.

Information on discards and on the sampling program was sent to the WG through ICES Accessions. The frequency of Nephrops occurrence in discards samples is very low. Discards are negligible in this fishery and mostly due to quality and not related to MLS (20 mm of carapace length). Only in 2013, the occurrence of Nephrops in discards samples was greater than $30 \%$ and a total amount of 3 t was estimated, with a high coefficient of variation ( $\mathrm{CV}=58 \%$ ).

### 13.2.2.2 Biological sampling

Length distributions for both males and females for the Portuguese trawl landings are obtained from samples taken weekly at the main auction port, Vila Real de Sto. António. Sampling frequency in 2014 was at the same level as in previous years, in the months in which fishing was open. The sampling data are raised to the total landings by market category, vessel and month.

The length compositions of the landings are presented in Tables 13.2.2a-b and Figures 13.2.2a-b. The number of samples and measured individuals are presented in Table 1.3.

### 13.2.2.3 Biomass indices from surveys

Since 1997, several groundfish (PtGFS-WIBTS-Q4) and crustacean trawl surveys (PTCTS UWTV FU 28-29) were carried out in FUs 28 and 29. Table 13.2.4 and Figure 13.2.1 shows the average Nephrops CPUEs (kg/h trawling) from the crustacean trawl surveys, which can be used as an overall biomass index. As the surveys were performed with a smaller mesh size than the commercial fishery, this information provides a better estimation of the abundance for the smaller lengths of Nephrops. There was an increase in the overall biomass index in the period 2003-2005, and also of small individuals in a particular juvenile concentration area in 2005, which could be an indication of higher recruitment.

The R/V "NORUEGA" had some technical problems in 2010 and could not trawl in areas deeper than 600 m . The survey plan had to be adapted accordingly. The CPUE value obtained for 2010, the highest from the series, was probably affected by this change. In 2011, due to engine failure, the survey did not cover the whole area of

Nephrops distribution. No CPUE index was presented for this year. Budgetary constraints of national scope turned unfeasible to repair the R/V NORUEGA and the chartering of another research vessel and therefore no survey was conducted in 2012.

The biomass index estimated from the 2013 survey is only comparable to the value of 2009, which covered the same area. Comparing the fraction of the area covered in 2011 and the same area in 2013, the biomass of Nephrops increased in the area of Alentejo (FU 28). The survey in 2011 did not cover the main area of concentration in Algarve (FU29). In recent years, there is a large uncertainty associated with the survey indices due to technical problems of the research vessel and partial coverage of the area of distribution.

The survey area was adapted in 2014 taking into account the information from the fishing grounds obtained from VMS data. The 2014 survey was carried out later than in previous years, after the peak of the fishing season and the biomass index was lower (Figure 13.2.1 and 13.2.3).

As shown in ICES (2012a), the distribution of survey indices is in very good agreement with the fishery CPUE spatial distribution. The correlation between the average annual CPUE from the fishery and the biomass index from the Crustacean survey until 2009 is also high. The values from recent years were not taken into account due to the R/V operation problems already referred.

In 2005 and 2007, some experiments to collect UWTV images from the Nephrops fishing grounds were made with a camera hanged from the trawl headline. In 2008, the images collected from 9 stations in FU 28 with the same procedure looked very promising. In 2009 survey, a two-beam laser pointer was attached to the camera and UWTV images were recorded from 58 of the 65 stations. The trawling speed and the turbidity were the main problems affecting the clarity of the image and the high variation of the height of the camera to the ground resulted in a variable field of view. In 2010 and 2011, no images were collected due to technical problems of the research vessel. It is not guaranteed that this method can be used for abundance estimation (information presented to SGNEPS 2012 - Study Group of Nephrops Surveys (ICES, 2012b).

### 13.2.2.4 Mean sizes

Mean carapace length (CL) data for males and females in the landings and surveys are presented for the period 1994-2014 (Table 13.2.5). Figure 13.2.1 shows the mean CL trends since 1984. The mean sizes of males and females have fluctuated along the period with no apparent trend.

### 13.2.2.5 Commercial catch-effort data

A standardization of the CPUE series was presented to WGHMM in 2008 (ICES, 2008, Silva, C. - WD 25) applying the generalized linear models (GLMs). The data used for this standardization were the crustacean logbooks for the period 1988-2007. The factors retained for the final model (year, month and vessel category) were those which contribute more than $1 \%$ to the overall variance. The model explains $17 \%$ to $19 \%$ of the variability, when using the CPUE in $\mathrm{kg} /$ day or $\mathrm{kg} /$ haul respectively.

Until 2010, this model was updated each year with the addition of new data.
The issue of effort estimation using standardized CPUE from GLMs or other methods taking into account the flexibility of the fleet in relation to target species was further developed in the WGHMM 2010 (ICES, 2010a) and during WKSHAKE2 (ICES, 2010b). Crustacean vessels are targeting two main species, rose shrimp and Norway lobster,
which have different market value. Depending on their abundance/availability, the effort is directed at one species or the other. In 2006, the landings of rose shrimp start to increase showing a change in the objectives of the fishery (Figure 13.2.3).

The effort is estimated using the CPUE of the fleet. If the CPUE of Nephrops decreased due to a change in target species (and consequently, fishing grounds), the effort might be overestimated.

The model of CPUE standardization used until 2010 never explained more than $20 \%$ of the variability (ICES, 2010a). The explanatory variables used were year, month and vessel-category. Considering the behaviour of the fleet in periods of high abundance of rose shrimp, new variables related to the catches of this species and the proportion of Nephrops in the total catch were incorporated. As the distributions of rose shrimp and Nephrops are fishing ground and depth dependent, the availability and use of VMS data could improve the standardization model, as suggested in Silva and Afonso-Dias, 2011 (WD to WKCPUEFFORT).

Taking all this into account, new variables as the fishing depth, the catches of rose shrimp and the proportion of Nephrops in the total crustacean catches were incorporated in the new model for CPUE standardization and presented to IBP Nephrops 2012 (Inter-Benchmark Protocol for Nephrops 2012, ICES, 2012c).

The IBP Nephrops did not come to a conclusion about the stock assessment method but the WG has agreed to use this new CPUE standardization for the trends based assessment and standardized effort estimation.

However, as VMS data are only available since 1998, the use of this method has shortened the length of the time series. In the models presented before, the CPUE was expressed in $\mathrm{kg} /$ day and the time series started in 1988. The CPUE in the new model is expressed in $\mathrm{kg} /$ hour, the time series starts 10 years later but the estimation of CPUE is based on more reliable effort data.

The overall analysis of the geo-referenced catches confirms the general preference of rose shrimp and Nephrops for grounds shallower and deeper than 400 m , respectively. These data also confirm that, in years of higher abundance of rose shrimp, a greater effort is allocated to depths shallower than 400 m . In what concerns the distribution of the fishing effort between the two Functional Units, FU29 represents in average 83\% of the total effort. However, the fishing areas (FUs) were found not significantly different and therefore removed from the model.

The factors and levels retained in the final model and updated to include more recent data were:

- year: 1998-2014
- month: 1 - 12
- depth interval: [100, 400[, [400, $800[,[800,1500]$
- $\log$ catch of rose shrimp: $[0,2[,[2,5]$
- proportion of Nephrops in the total catch of crustaceans: $[0,0.25[,[0.25,1]$
- and vessel category: A (standard), B and C. These two categories correspond to vessels less or more productive than the standard type.

The choice of the final model was based on the highest value of explained variance and the smallest AIC. In 2014 assessment, with the data from 1998-2013, the model explained $47 \%$ of the total variability, with the proportion of Nephrops in the crustacean
catches as the most important factor (Table 13.2.6). This year, the same model was updated with one more year of data, but the explained deviance has reduced to $33.5 \%$. One possible explanation is that in the last two years, fishing does not cover the whole year, due to the reduced quota.
Figure 13.2.4 shows the annual observed CPUE and the estimates from the model, considering the depth interval class [400, 800[, log catch of rose shrimp class [0, 2[, the category of proportion of Nephrops $[0.25,1]$ and vessel category A as the reference factors for Nephrops target CPUE.
The correlation found between the CPUE series derived from the model presented here and the biomass indices from the Crustacean surveys (not considering the estimates after 2009, for the reasons explained before) is high and gives confidence that CPUE is reflecting the abundance of Nephrops in FU 28 and 29.

The effort in 2003-2004 corresponds to only eleven months of fleet operation for each year as the crustacean fishery was experimentally closed in January 2003 and 30 days for Nephrops in September - October 2004.

A Portuguese national regulation (Portaria no. 1142, 13 ${ }^{\text {th }}$ September 2004) closed the crustacean fishery in January-February 2005 and enforced a ban in Nephrops fishing for 30 days in September - October 2005. As a result, the effort in 2005 corresponds to nine months.

The recovery plan for southern hake and Iberian Nephrops stocks was approved in December 2005 and initiated at the end of January 2006. This recovery plan includes a reduction of $10 \%$ in F relative to the previous year (Council Regulation (EC) No $2166 / 2005$ ). As a result, the number of fishing days per vessel was progressively reduced. Additional days were allocated in 2010 to Spanish and Portuguese vessels on the basis of permanent cessation of vessels from each country (Commission Decisions nos. 2010/370/EU and 2010/415/EU).

Besides this effort reduction, the Council Regulation (EC) No 850/98 was amended with the introduction of two boxes in Division IXa, one of them located in FU 28. In the period of higher catches (May-August), this box is closed for Nephrops fishing (Council Regulation (EC) No 2166/2005). By way of derogation, fishing with bottom trawls in these areas and periods are authorised provided that the by-catch of Norway lobster does not exceed $2 \%$ of the total weight of the catch. The same applies to creels that do not catch Nephrops.
The effort reduction measures were combined with a national regulation closing the crustacean fishery every year in January (Portaria no. 43, 12 th January 2006). As a result of these measures, the nominal effort in 2006 to 2011 corresponds to 11 months each year.
In the period 1999-2001, standardized fishing effort increased substantially, remaining high until 2004-2005 (Table 13.2.3 and Figure 13.2.1), with an exceptional drop in 2003. After 2005, the effort presents a decreasing trend until 2009. The effort decline may be related to the effort management measures but also to effort shift to rose shrimp, which presented a large increase in abundance and landings in the period 2007-2011 (Figure 13.2.4).

The standardized effort increased in 2012 due to a higher catch from Portuguese fleet and to the provision of Spanish catches in this year. As stated in section 13.2.2.1, Spanish vessels are licensed for crustaceans in these FUs under a bilateral agreement since

2004, but no official data were available prior to 2011. In 2013, due to the lower availability of rose shrimp and the increase in abundance of Norway lobster, the Portuguese quota was fished until September and the Portuguese crustacean fleet had to stop the operation or to target other crustacean species, resulting in effort reduction. The same happened in 2014, but the industry decided to stop earlier the fishery and save part of the quota to be fished in November-December In regard to the Spanish fleet, the number of fishing days has reduced, due to sanctions imposed by EC related to the catches over quota in 2012, affecting also the operation of this fleet in the Portuguese fishing grounds.

### 13.2.3 Assessment

As the perception of the stock did not change from previous year, no update of the assessment was performed.

### 13.2.4 Short-term Projections

No projections were performed.

### 13.2.5 Biological reference points

No biological reference points are defined for these stocks.
Biological reference points estimated on the basis of the Yield per Recruit curve were presented in ICES (2011).

### 13.2.6 Management considerations

Nephrops is taken by a multi-species and mixed bottom trawl fishery.
A recovery plan for southern hake and Iberian Nephrops stocks was approved in December 2005 and in action since the end of January 2006. This recovery plan includes a reduction of $10 \%$ in the hake F relative to the previous year and TAC set accordingly, within the limits of $\pm 15 \%$ of the previous year TAC (Council Regulation (EC) No 2166/2005). Although no clear targets were defined for Norway lobster stocks in the plan, the same $10 \%$ reduction has been applied to these stocks effort and TAC. The number of allowed fishing days is set in each year regulations (Council Regulations (EC) Nos. 51/2006, 41/2007, 40/2008, 43/2009, 53/2010, 57/2011, 43/2012, 39/2013, 43/2014 and $104 / 2015$ ). The recovery plan target and rules have not been changed since it was implemented.

Besides the recovery plan, the Council Regulation (EC) No 850/98 was amended with the introduction of two boxes in Division IXa, one of them located in FU 28. In the period of higher catches (May-August), these boxes are closed for Nephrops fishing (Council Regulation (EC) No 2166/2005). By derogation, fishing with bottom trawls in these areas and periods are authorised provided that the by-catch of Norway lobster does not exceed $2 \%$ of the total weight of the catch. The same applies to creels that do not catch Nephrops.

With the aim of reducing effort on crustacean stocks, a Portuguese national regulation (Portaria no. 1142, $13^{\text {th }}$ September 2004) closed the crustacean fishery in January-February 2005 and enforced a ban in Nephrops fishing for 30 days in September - October 2005, in FUs 28-29. This regulation was revoked in January 2006, after the entry in force of the recovery plan and the amendment to the Council Regulation (EC) No 850/98, keeping only one month of closure of the crustacean fishery in January (Portaria no. 43/2006, $12^{\text {th }}$ January 2006).

Portugal and Spain have bilateral agreements for fishing in each other waters. The agreement for the period 2004-2013 was reviewed and extended for 2014 and 2015. Under this agreement a number of Spanish trawlers are licensed to fish crustaceans in Portuguese waters. No information from landings of these vessels is available for the years prior to 2011.

13.3.1.3 ICES Advice for 2015 and Management applicable for 2015 and 2016

## ICES Advice for 2015

The advice for these Nephrops stocks is biennial and valid for 2015 and 2016.
Based on the ICES approach for data-limited stocks, ICES advises that catches should be no more than 95 tonnes. All catches are assumed to be landed.

To protect the stock in this Functional Unit, ICES advices that management area should be consistent with the assess area. Therefore, management should be implemented at the Functional Unit level.

## Management applicable for 2014 and 2015

A recovery plan for southern hake and Iberian Nephrops stocks has been in force since the end of January 2006. The aim of the recovery plan is to rebuild the stocks within 10 years, with a reduction of $10 \%$ in F relative to the previous year and the TAC set accordingly (Council Regulation (EC) No. 2166/2005).

An increase of mesh size to 55 mm was established since September of 2009 (Orden ARM/2515/2009) for the bottom trawl fleet.

The TAC set for the whole Division IXa was 221 t for 2014 and 254 t for 2015, respectively, of which no more than $6 \%$ may be taken in FUs 26 and 27. The maximum number of fishing days per vessel was fixed at 127 and 114 days for Spanish vessels and at 126 and 113 days for Portuguese vessels for these two years (Annex IIb of Council Regulations nos. 43/2014 and 104/2015). The number of fishing days included in these regulations is not applicable to the Gulf of Cadiz (FU 30), which has a different regime.

### 13.3.2 Data

### 13.3.2.1 Commercial catch and discard

Up to 2010, landings have been estimated by the WG based on IEO scientific estimations. The information was compiled by IEO from sale sheets and Owners Associations and the Nephrops landings allocation was carried out based on landing port criteria. Since 2011, the Spanish Authority for Fisheries (Secretaría General de Pesca, SGP) who is also the National Authority for the Data Collection Framework established a new policy and general approach in the provision of official data on catches and fishing effort. So, since 2011 Nephrops landings are official landings.

Unlike the IEO scientific estimates, official landings are derived from logbooks. This source of information allows the landings disaggregation by ICES statistical rectangles.

In WGHMM 2013 it was noticed that some Nephrops catches were recorded into statistical rectangles outside of the FU 30 definition. In 2012 and 2013, Nephrops catches recorded into statistical rectangles outside of this FU were considered as part of the landings in FU 30. In 2014 Spanish landings of Nephrops have been uploaded to InterCatch broken down by ICES statistical rectangle for the first time according to the 2014 ICES Data Call requirements. However, only the landings recorded inside ICES statistical rectangles defined as FU 30 were uploaded to InterCatch, which correspond to $83.8 \%$ of 2014 landings (WD № 3 Castro). As the outer rectangles were not defined in InterCatch, the remaining landings couldn't be upload this year but this will be for next year WG.

Landings in this FU are reported by Spain and also minor quantities by Portugal. Since WGHMM in 2010, Nephrops landings in Ayamonte port were incorporated in the Gulf of Cadiz time series of landings, as well as directed effort and LPUE from 2002 (Tables 13.3.1 and 13.3.4). Nephrops total landings in FU 30 decreased from 108 t in 1994 to 49 t in 1996. After that, there has been an increasing trend, reaching 307 t in 2003, dropping to 246 t in 2005-2006 (with the exception for the year 2004 when a decrease of more than $50 \%$ was observed). In the 2008-2012 periods, landings remained relatively stable around 100 t but decreased to 26 t in 2013 and 15 t in 2014. The reason for this drop is that the quota in 2012 was exceeded and the European Commission applied a sanction to be paid in 3 years. So, the Nephrops fishery was closed in 2013 and 2014 and vessels could only go fishing Nephrops a few days in summer and winter. In addition, a modification of the regulation implemented for the Spanish Administration for the Gulf of Cadiz grounds in 2014 (Orden AAA/1710/2014) establishes the assignment of Nephrops quotas by vessel. These facts may have caused unreported Nephrops landings and as consequence a decrease of landings in 2014.

Information on discards was sent to the WG through InterCatch. The discarding rate of Nephrops in this fishery fluctuates annually but is always low and the discards are considered negligible (Table 13.3.2). No Nephrops discards were recorded in 2011-2014 period with the exception for the year 2013 which represented 3.7\%. Figure 13.3.2 shows the estimated length frequency distributions of the discarded and retained Nephrops by trip for the annual discarding program.

### 13.3.2.2 Biological sampling

The sampling level for the species is given in Table 1.3.
Figure 13.3.3a and 13.3.3b shows the annual landings length distribution for males, females and both sexes combined during the period 2001-2014. The length composition of landings is biased for the period 2001 to 2005 since the sampling of landings was not stratified by commercial categories (Silva et al., 2006). A new sampling scheme was applied from 2006 to 2008 and the information was more reliable. The mean sizes for both sexes remained relatively stable after the sampling scheme was changed, around 29 mm CL for sexes combined.

Since 2009, onboard concurrent sampling is carried out, as required by the DCF (Reg. EC 1343/2007). Outside of the Nephrops fishing season, a higher proportion of observer trips are likely to not cover Nephrops catches whereas when the directed Nephrops sampling were carried out in harbours in the past, the length distribution of landings were covered in all months. This fact could reduce the consistency of the length distribution of the catches in 2011 and 2012. The number of monthly sampling in 2013 and 2014 was probably influenced by the closure of Nephrops fishery.

Mean size of males and females in Nephrops landings in the period 2001-2014 are shown in Figure 13.3.1. The mean sizes show a slight increasing trend from 2006 to 2012. In 2013 and 2014, a decline of the mean size was observed.

### 13.3.2.3 Abundance indices from surveys

The biomass and the abundance indices of Nephrops by depth strata, estimated from the Spanish bottom trawl spring surveys (SPGF-cspr-WIBTS-Q1) carried out from 1993 to 2014 are shown in Table 13.3.3.

Two different periods can be observed in the time series. From 1993 to 1998 the overall abundance index trend was decreasing, while from 1998 to 2009 the index has remained stable although fluctuating widely in some years, except in 2004, which value was the lowest value in the time series. In 2010 the deeper strata ( $500-700 \mathrm{~m}$ ) were not sampled due to a reduction in number of the survey the days, as a consequence of adverse weather conditions. Therefore, only the abundance index for the strata 200-500 m is available for 2010 (Table 13.3.3) and its value is similar to the corresponding strata in previous year. The abundance index was lower in 2011 and 2012 but it increased strongly in 2013 and 2014, reaching the highest value of the time series in the last year (Table 13.3.3). This survey is not specifically directed to Nephrops and is not carried out during the main Nephrops fishing season but it shows a similar trend to the commercial LPUE.

The length distributions of Nephrops obtained in the Spanish bottom trawl spring surveys (SPGF-cspr-WIBTS-Q1) during the period 2001-2014 are presented in Figure 13.3.6. The time series of Nephrops mean sizes for males, females and combined sexes obtained in these surveys are shown in Figure 13.3.6. No apparent trends are observed. The mean size ranged in 2014 was 37.3 mm carapace length for males and 30.1 for females.

### 13.3.2.4 Commercial catch- Effort data

Figure 13.3 .1 and Table 13.3 .4 show directed Nephrops effort estimates and LPUE series modified after the incorporation of data from Ayamonte port since 2002.

The directed fishing effort trend is clearly increasing from 1994 to 2005, where the highest value of the time series was recorded ( 4336 fishing days). After that, the effort declined to 2008 ( $73 \%$ ) remaining relatively stable during the 2008-2012 period. The closure of the Nephrops fishery resulted in a decrease of the fishing effort in 2013 (262 fishing days) and 2014 (293 fishing days) in relation to the previous years (Figure 13.3.1)

LPUE obtained from the directed effort shows a gradual decrease from 1994 to 1998. After 1998, the trend slightly increases until 2003. In 2004, the LPUE decreases to the lowest value recorded ( $44.3 \mathrm{Kg} /$ fishing day). LPUE then increased until 2008 around $60 \%$. Since 2008 LPUE have declined to $50 \mathrm{Kg} /$ fishing day in 2009 and $45.5 \mathrm{Kg} /$ fishing day in 2010 (about $30 \%$ less with respect to 2008). Since 2010, LPUE shows an increasing trend with a high rise in 2013 but drop in 2014 (Figure 13.3.1). LPUE in 2013 and 2014 must be taken with caution as it does not cover the whole year due of the closure of the Nephrops fishery the most part of the year which increases the uncertainty associated with the LPUE index. Moreover, the assignment of Nephrops quotas by vessel implemented in 2014 might have caused unreported landings and to contribute to the increases the uncertainty of the commercial index.
The overall LPUE trend is quite similar to the abundance survey index in the stratum of 200-700 m from 1996 to 2013 (no survey was carried out in 2003) despite the survey
index have fluctuated in some years (Figure 13.3.4). The lowest values were detected in 2004 in both series. In 2008, the abundance survey index was well above the commercial LPUE, however, the abundance index drop in 2009 agrees with the commercial LPUE. This fact may be explained by the increase of the rose shrimp abundance in 2008. The increased abundance of rose shrimp is believed to have led to a change in the objectives of the fishery, as rose shrimp achieves a higher market value and its fishing grounds, shallower ( $90-380 \mathrm{~m}$ ) and closer to the coast. In 2011 and 2012, an increase of the directed commercial LPUE was observed but differently, the abundance index of spring survey decreased. In contrast, a strong increase of the survey abundance index was observed in 2013 and 2014. The value of the survey index in 2014 was the highest recorded in the whole time series indicating an increase of the Nephrops abundance in FU 30 (Figure 13.3.5).

### 13.3.3 Assessment

The update of the LPUE series and abundance survey index shows two conflicting signals. The LPUE decreasing while the survey index is increasing however, WG express concerns over the ability of those two indexes to reflect variations in the abundance in 2013 and 2014. The WG considers that no new information is available to change the perception of the status of the stock.

### 13.3.4 Biological reference points

No reference points are defined for this stock.

### 13.3.5 Management considerations

Nephrops fishery is taken in mixed bottom trawl fisheries; therefore HCRs applied to other species will affect this stock.

In 2013 and 2014, Nephrops fishery was closed the most part of the year because the quota in 2012 was exceeded and a sanction for the European Commission to be paid in 3 years was applied.

A Recovery Plan for the Iberian stocks of hake and Nephrops was approved in December 2005 (CE 2166/2005). This recovery plan includes a reduction of $10 \%$ in F relative to the previous year and TAC set accordingly, within the limits of $\pm 15 \%$ of the previous year TAC. By derogation, a different method of effort management method is applied to the Gulf of Cadiz.

Different Fishing Plans for the Gulf of Cadiz have been established by the Spanish Administration since 2004 in order to reduce the fishing effort of the bottom trawl fleet (ORDENES APA/3423/2004, APA/2858/2005, APA/2883/2006, APA/2801/2007, ARM/2515/2009, ARM/58/2010, ARM/2457/2010; AAA/627/2013). Last plan continue establishing a closed fishing season to 45 days, between September and November, plus 5 additional days to be selected by the ship owner during the duration of this Plan. The potential effect of the closed seasons on the Nephrops population has not been evaluated. Additionally, an increase of mesh size to 55 mm or more was implemented at the end of 2009 in order to reduce discards of individuals below the minimum landing size. In 2014, a modification of last Fishing Plan for the Gulf of Cadiz was established (AAA/1710/2014). This new regulation establishes an assignation of the Nephrops quotas by vessel.
Regulations were established by the Regional Administration with the aim of distributing the fishing effort throughout the year (Resolutions: $13^{\text {th }}$ February 2008, BOJA n ${ }^{\text {o }}$

40; $16^{\text {th }}$ February 2009, BOJA no 36 ; $23^{\text {th }}$ November 2009, BOJA n ${ }^{\text {o }} 235$; $15^{\text {th }}$ October 2010, BOJA no 209). These regional regulations control the days and time when the Gulf of Cadiz bottom trawl fleet can enter or leave fishing ports. Although the regulations vary among them, they generally allow a large flexibility during late spring and summer months (e.g. the 2010 Regulation established a continuous period from Monday 3 am to Thursday 9 pm during May-August, that was implemented in 2011), which is the main Nephrops fishing season, with more restricted time period in other months. This flexibility in summer months might have induced fleets from the ports closer to Nephrops grounds, such as Ayamonte or Isla Cristina, to direct their fishing effort to this species.

## 14 European Seabass in Division VIIIa,b

### 14.1 ICES advice applicable to 2014 (June 2014)

"There are no new data available that change the perception of the stock; therefore, the advice for this fishery in 2015 is the same as the advice for 2014. The advice for 2014 was (see ICES, 2013): Based on the ICES approach to data-limited stocks, ICES advises that commercial catches should be no more than 1890 tonnes. Discards are considered as negligible, therefore, all catches are assumed to be landed [...]".

### 14.2 General

### 14.2.1 Stock ID and sub-stock structure

Bass Dicentrarchus labrax is a widely distributed species in northeast Atlantic shelf waters with a range from southern Norway, through the North Sea, the Irish Sea, the Bay of Biscay, the Mediterranean and the Black Sea to North-west Africa. The species is at the northern limits of its range around the British Isles and southern Scandinavia. Stock identity of European seabass was reviewed by WGNEW 2012 and further considered at ICES IBP-NEW 2012. The other stock units defined for sea bass are: west of Scotland and Ireland (VIa and VIIb,j); IVbc + VIIa,d-h; VIIIab and the more southerly population in VIIIc IXa (Figure 14-1). The IBP New 2012 reports that it is clear that further studies are needed on sea bass stock identity, using conventional and electronic tagging, genetics and other individual and population markers (e.g. otolith microchemistry and shape), together with data on spawning distribution, larval transport and VMS data for vessels tracking migrating sea bass shoals, to con-firm and quantify the exchange rate of sea bass between sea areas that could form management units for this stock.

In the absence of new information the pragmatic view of WGBIE2015 is to continue to assume the presence of discrete sea bass stocks off southern Ireland and in the Bay of Biscay (VIIIab) and iberian waters (VIIIc, IXa).

Figure 14-1 : stock seabass units defined at ICES (IBP new 2012)

### 14.2.2 Management applicable to 2014

Sea bass are not subject to EU TACs and quotas. Under EU regulation, the minimum landing size (MLS) of bass in the Northeast Atlantic is 36 cm total length, A variety of national restrictions on commercial bass fishing are also in place. These include:

- A landings limit of 5 t /boat/week for French and UK trawlers landing bass (which is not based on a biological point of reference). In France from 2012, following the implementation of a national licensing system for commercial gears targeting sea bass, the landings limits have slightly changed (depending on season and gear) ${ }^{1}$.
- A licensing system from 2012 in France for commercial gears targeting sea bass in order to fix the level of the French commercial fishery.
- A MLS of 42 cm for the French recreational fisheries has been implemented in 2013.
- Voluntary closed season from February to mid-March for longline and handline bass fisheries in Brittany, France;

### 14.2.3 Management applicable to 2015

No new management plan is known at present in the Bay of Biscay. For information in IVbc and VIIa,d-h (North Sea, Channel, Celtic Sea and Irish Sea) the European Council has adopted measures to help sea bass recover (Recent scientific analyses have reinforced previous concerns about the state of the stock and advised urgently to reduce fishing by $80 \%$. Effective emergency measures in January 2015 placed a ban on targeting the fish stock by pair-trawling while it is reproducing, during the spawning season, which runs until the end of April 2015. For recreational fishing the decision will mean the introduction of a limit of three fish per day per angler. This will be complemented by further measures to ensure that all those who fish sea bass make a balanced and fair contribution to saving the stock. In order to help the stock of sea bass recover, more action is needed to address the impact of all other commercial and recreational fishing activities.

### 14.3 Fisheries data

### 14.3.1 Commercial landings data

Seabass in the Bay of Biscay, are targeted by France (more than $90 \%$ of international landings) by line fisheries which take place mainly from July to October, by nets, pelagic trawlers, and in a mixed bottom trawl fisheries from November to April on pre spawning and spawning grounds when seabass is aggregated. In 2014 nets represent $39 \%$ of the landings of the area, lines (handlines+longlines) $27 \%$, bottom trawl $16 \%$, and pelagic trawl 7\% (but It has to be note that pelagic trawlers were used from 2000 to 2008 to catch around $25 \%$ of the landings of the area decreasing to 9 (the pelagic fishery take place at present essentially in the Channel before 2015).

A high increase in the french landings of nets is observed from 2011. An average of 585 tons during the period 2000-2012 is landed. In 2013, 834 tons have been landed, and 1131 tons in 2014. The main reason is the decrease of sole quotas from 2011 and an effort report on seabass which become more targeted, combined with good weather condition in 2014 and an increase in fishing technicality. French landings by metier are presented in Figure 14-2

Spain is responsible for 3\% of the catches of the area (VIIIb essentially) in 2014, mainly with bottom trawlers. Spanish bass landings from Division VIIIa,b,d have increased to around 20 tons in the 90 's to around 150 tons in the middle of the 2000's, then a peak to 317 tons in 2011. 91 tons have been landed in 2014

UK landings from this area are very low, usually inferior to 5 tons per year.
Recreational fisheries are an important part of the total removals but these are not accurately quantified. Figure 14-2 presents official and ices landings.

### 14.3.2 Length compositions: commercial landings

Table 14-2 gives fleet-raised length compositions for all French gears

### 14.3.3 Commercial discards

### 14.3.3.1 France

Discarding of sea bass by commercial fisheries can occur where fishing takes place in areas with bass smaller than the minimum landing size $(36 \mathrm{~cm}$ in most European countries), and where mesh sizes $<100 \mathrm{~mm}$ are in use. For $2009 \mathrm{it}^{\prime}$ s estimated to be 44 tons, for 201044 tons, for 201120 tons, for 201237 tons and for 201368 tons

Discarding is thought to be low because of the high value of the fish. In 2014, very low number of sebass have been sampled ( 160 fish have been measured at sea in 2014, 65\% for bottom trawlers, $28 \%$ for nets and $7 \%$ longlines and handlines). This cannot allowed to raise raw data to the whole fishery (DCRcvIndicator $=0.97$ ). Neverless this may indicate discarding is low in the area.

### 14.3.3.2 Spain

Observer data from Spanish vessels fishing in Areas VIII, have shown there was no seabass discard from 2003. No information in 2013 and 2014 were available on discards for WGBIE.

### 14.3.4 Recreational catches

Recreational marine fishery surveys in Europe are still at an early stage in development (ICES WGRFS 2012). A french study targeting sea bass was conducted between 2009 and 2011 in VIIIa, VIIIb, VIIe, VIIh, VIId, Ivc. Estimates of sea bass catches were obtained from a panel of 121 recreational fishermen recruited during a random digit dialling screening survey of 15000 households in the targeted districts (Atlantic and Chanel). The estimated recreational catch of bass in the Bay of Biscay and in the Channel was $3,170 \mathrm{t}$ of which $2,350 \mathrm{t}$ was kept and 830 t released. The precision of the the combined Biscay \& Channel estimate is relatively low (CV $=-26 \%$; note that the figure of $51 \%$ given in IBP-NEW 2012 was incorrect). This makes the confidence interval at $95 \%$ of the average (3170t) to [1554t;4786t].

A new survey was conducted from July 2011 to December 2012, based on a similar methodology to the previous study (not only on sea bass this time, but also on other
marine species including crustaceans and cephalopods). A random digit dialling screening survey of 16130 households led to the recruitment of a panel of 183 fishermen to keep logbooks. In parallel, 151 fishermen were recruited on site by the Promopeche association, and 30 more via the sea bass fishermen panel set up in 2009. This resulted in 364 panel members keeping logbooks describing their catches (species, weight, size, etc.) The focus of the survey on sea bass shows that in Atlantic (Bay of Biscay and Channel), the estimated recreational catch of bass in 2012 was 3922 t of which 3146 t was kept and 776 t released. At this time results have to be considered as provisional, (results split between Bay and Biscay and Channel are not available yet with relative standard error).

### 14.3.5 Abundance Indices

No pre and post-recruit surveys are available for the area. In 2015 a study "French Logbook data analysis 2000-2013: possible contribution to the discussion of the sea bass stock(s) structure/annual abundance indices. Alain Laurec, M.Drogou"has been conducted and presented in a Working Document (reference : WD_12).

### 14.4 Assessment

WGBIE 2015 propose to upgrade stock VIIIab from category 5 to category 3.2.
The working document (A.Laurec;M.Drogou 2015) has been presented to WGBIE 2015. Annual indices of abundance have been assessed by the group. The assessment is also based on the analysis of lpues and total catches. For data-limited stocks for which a biomass index is available, ICES uses a harvest control rule based on an index-adjusted status quo catch. The advice is based on a comparison of the 3 most recent biomass index values with the 4 preceding values, combined with recent catch or landings data.

Any visual check of apparent abundance time series reveals the combination of a strong seasonal effect, a multiannual trend and apparent added noise. The strongest seasonal effect corresponds to what will be interpreted as spawning migrations and concentrations which take place in late autumn and winter. This is why it has been decided not to use the usual calendar year from January to December, but 12 months period from July to the following June month, the apparent abundance being for most squares low in June-July, without major changes between June and the following July month. The analysis has also been carried out using the basic calendar year on a data series from 2000 to 2013. It led to the same seasonal patterns which are simply more difficult to follow between december and january, when the main part of the landings are taken which corresponds to the spawning season in the Bay of Biscay).

The Working Group decided to retain the seasonal LPUE index as each yearly index fully covers the spawning season (December to March) when the main fishery occurs.

Table 14.3 and Figure 14.3 present Abundance Index used for assesment.
For calculating catch option, mean of landings from 2007 to 2013 has been calculated. A large period has been retained because of the seabass long life duration (up to 28 years)

For Seabass the biomass is estimated to have increased by more than $30 \%$ between the periods 2008-2011 (average of the 4 years) and 2012-2013 (average of the 3 years). This implies an increase in landings of at most $20 \%$. When the uncertainty cap in relation to the average landings of the last 7 years (2007-2013) is applied, this corresponds to landings in 2016 of no more than 3 037t. Considering that landings in the net fisheries has
increased significantly (the bulk of the net fishery historically targets sole and to a lesser extent seabass but reports effort on seabass increasing after the decrease of the sole quota from 2012), an additional precautionary action is needed. This would lead to landings of no more than 2437 t .
Discards are known to take place but are not fully quantified. Anecdotal information suggests that discards may be very low in the area.

### 14.5 Future Research and data requirements

There are several important limitations to knowledge of sea bass populations, and deficiencies in data, that should be addressed in order to improve the assessments and advice for sea bass in the NE Atlantic. WGBIE 2015 makes the following recommendations:

The establishment of dedicated surveys on nurseries and tagging data on small fish could provide valuable information on trends in abundance and population structure of bass

Recruitment indices are needed for a wider geographic range including the Celtic/Irish Sea and Biscay areas.

Further research is needed to better understand the spatial dynamics of sea bass (mixing between ICES areas; effects of site fidelity on fishery impacts; spawning site recruitment ground linkages; environmental influences)

Studies are needed to investigate the accuracy/bias in ageing, and errors due to age sampling schemes historically

Continued estimation of recreational catches is needed across the stock range, and information to evaluate historical trends in recreational effort and catches would be beneficial for interpreting changes in age-length compositions over time.

### 14.6 Management plans

No management plan is known at present for the VIIIab stock.

### 14.7 Management consideration

Sea bass are characterised by slow growth, late maturity and low natural mortality on adults, which imply the need for comparatively low rates of fishing mortality to avoid depletion of spawning potential in each year class. In the IVbc, VIIa, d-h stock, dynamic of the stock is closely dependant to some year of good or very poor recruitment. It could be also the case in the Bay of Biscay.

The importance of sea bass to recreational fisheries, artisanal and other inshore commercial fisheries and large-scale offshore fisheries in different regions means that resource sharing is an important management consideration

The effects of targeting of offshore spawning aggregations of sea bass are poorly understood, particularly how the fishing effort is distributed in relation to mixing of fish from different nursery grounds or summer feeding grounds, given the strong site fidelity of sea bass.
As bass is, at present, a non-TAC species, there is potential for displacement of fishing effort from other species with limiting quotas as observed with nets in Bay of Biscay.

With no effective control on the fishery to limit the increase of the landings as observed in 2014, risks are taken unless strong year classes are produced.

### 14.8 Recommendations for next benchmark assessment

WGBIE proposes a benchmark for 2017 to :
-Develop assessment methods, possibly in conjunction with the other stocks of seabass
-Carry out a quality check of all seabass data for the Bay of Biscay.

## 15 European Seabass in Division VIIIc, IXa

### 15.1 ICES advice applicable to 2014 (June 2014)

"There are no new data available that change the perception of the stock. Therefore, the advice for this fishery in 2015 is the same as the advice for 2014 (see ICES, 2013): Based on ICES approach to data-limited stocks, ICES advises that commercial catches should be no more than 598 t . All commercial catches are assumed to be landed. Recreational catches cannot be quantified; therefore, total catches cannot be calculated"

### 15.2 General

### 15.2.1 Stock ID and sub-stock structure

Bass Dicentrarchus labrax is a widely distributed species in northeast Atlantic shelf waters with a range from southern Norway, through the North Sea, the Irish Sea, the Bay of Biscay, the Mediterranean and the Black Sea to North-west Africa. The species is at the northern limits of its range around the British Isles and southern Scandinavia. Stock identity of European seabass was reviewed by WGNEW 2012 and further considered at ICES IBP-NEW 2012. The other stock units defined for sea bass are: west of Scotland and Ireland (VIa and VIIb,j); IVbc + VIIa,d-h; VIIIab and the more southerly population in VIIIc IXa (Figure 15-1). The IBP New 2012 reports that it is clear that further studies are needed on sea bass stock identity, using conventional and electronic tagging, genetics and other individual and population markers (e.g. otolith microchemistry and shape), together with data on spawning distribution, larval transport and VMS data for vessels tracking migrating sea bass shoals, to con-firm and quantify the exchange rate of sea bass between sea areas that could form management units for this stock.

In the absence of new information the pragmatic view of WGBIE2015 is to continue to assume the presence of discrete sea bass stocks off southern Ireland and in the Bay of Biscay (VIIIab) and iberian waters (VIIIc, IXa).

Figure 15-1: stock seabass units defined at ICES (IBP new 2012)

### 15.2.2 Management applicable to 2014

Sea bass are not subject to EU TACs and quotas. Under EU regulation, the minimum landing size (MLS) of bass in the Northeast Atlantic is 36 cm total length, A variety of national restrictions on commercial bass fishing are also in place. These include:

Seabass are not subject to EU TACs and quotas. Under EU regulation, the MLS of sea bass in the Northeast Atlantic is 36 cm total length (EC regulation 850/98). A variety of national restrictions on commercial fishing for each metier also apply to sea bass. The measures affecting recreational fisheries in Portugal include gear restrictions, a minimum landing size equal to the commercial fishery MLS $(36 \mathrm{~cm})$, the total catch of fish and cephalopods by each fisher must be less than 10 kg per day, and prohibition on the sale of catch.

### 15.2.3 Management applicable to 2015

No new management plan is known at present in the Bay of Biscay. For information in IVbc and VIIa,d-h (North Sea, Channel, Celtic Sea and Irish Sea) the European Council has adopted measures to help sea bass recover (Recent scientific analyses have reinforced previous concerns about the state of the stock and advised urgently to reduce fishing by $80 \%$. Effective emergency measures in January 2015 placed a ban on targeting the fish stock by pair-trawling while it is reproducing, during the spawning season, which runs until the end of April 2015. For recreational fishing the decision will mean the introduction of a limit of three fish per day per angler. This will be complemented by further measures to ensure that all those who fish sea bass make a balanced and fair contribution to saving the stock. In order to help the stock of sea bass recover, more action is needed to address the impact of all other commercial and recreational fishing activities.

### 15.3 Fisheries data

### 15.3.1 Commercial landings data

Landings series are given in Table 15-1 and are derived from :
i) Official statistics recorded in the Fishstat database since around the mid1970s.
ii ) Spanish landings for 2007-2011 from sale notes
iii ) Portuguese estimated landings from 1986 to 2011 including distinction between Dicentrarchus labrax and punctatus.

Spanish and Portuguese vessels represent almost of the total annual landings in the area IXa and VIIIc. Commercial landings represent 917 tons in 2014. A peak of landings is observed in the early 90 's and in 2013, reaching more than 1000 tons, and lowest landings ( 637 tons) have been observed in 2004. Artisanal fisheries are mainly observed in this area. In 2014, in the all area, landings were equivalent between Spain and Portugal. However Landings from Portugal are only from the IXa area, while the Spanish landings are distributed between the two zones IXa and VIIIc (respectively (130 tons and 247 tons).

### 15.3.2 Commercial discards

Portugal: Sea bass discards are recorded by the DCF on-board sampling programme. The Portuguese on-board sampling is not covering the Sea Bass fishing area.No discards are observed.

Spain: No bass discards were observed for any metier in the 2003-2014 periods.

### 15.3.3 Recreational catches

Recreational marine fishery surveys in Europe are still at an early stage in development (ICES WGRFS 2012).

### 15.4 Management plans

No management plan is known at present for the VIIIc, IXa stock.

* Preliminary
*-Official landings have been extracted from the Ices Official Catch Statistics Web page (04May 2015) for "BSS" and area VIIIc, IXa and IX (IX has been retained for Portuguese statistics because reported as IXa prior 2007).
***Difference between Ices Statistics and official Statistics are mainly due prior 2006 to Portugal statistics : before 2006 most of the sea bass catches were registered under the code BSE, i.e. (Dicentrarchus sp.). After the DCF implementation there was a progressive increase in the correct identification of species in the official statistics (BSS increase, BSE decrease) who consider Dicentrarchus sp landings minus $2.3 \%$ of Dicentrarchus punctatus based on DCF market and on-board sampling between 2008 and 2012)

## 16 Plaice in Subarea VIII and Division IXa

Plaice (Pleuronectes platessa) are caught as a bycatch by various fleets and gear types covering small-scale artisanal and trawl fisheries. Portugal and France are the main participants in this fishery with Spain playing a minor role. Present fishery statistics are considered to be preliminary as there are concerns about the reliability of the French data from 2008-09. Landings may also contain misidentified flounder (Platichthys flesus) as they are often confounded at sales auctions in Portugal. The quantity of discarding is uncertain. For these reasons, the landings are unlikely to be a good indicator of total removals and ICES considers that it is not possible to quantify the catches.

This stock from is currently ranked as a Data Limited Stock in category 5.2 as only landings data are available (Table 16.1); however, all the stocks covered by the current DCF sampling programme have been proposed to be upgraded to category 4 , because of the availability of biological information. For the first time this year national laboratories were requested via ICES Data call to provide information on quantity and length composition of commercial landings and discards. However, no length information was submitted. Quantity of landings and discards were provided by Spain, France, Portugal and Belgium (Table 16.2).

Plaice were not present in sufficient numbers to provide survey abundance indices and no commercial indices were available. Other approaches should be considered in order to obtain fishery independent information.
Biological information needs to be compiled. However, issues concerning the quality of landings statistics in addition to the lack of survey or commercial abundance indices need to be resolved before a new assessment is developed. As this species is at the southern extent of its range in the Bay of Biscay and Iberian Peninsula (Figure 16.1) perhaps merging of the northern and southern stocks would provide the best opportunity to improve the assessment.

## 17 Pollack in Subarea VIII and Division IXa

The official landing statistics have been updated in table 17. 1 for 2014. In the 2014 advice ICES advises that catches should decrease by $20 \%$ in relation to the last three years' average landings (2011-2013), corresponding to landings of no more than 1316 tonnes. No additional data were provided in 2014 and landing statistics do not show any remarkable changes so the group considered there is no basis to change the advice basis.

However, since the landing data are now available, the working group considered that it is now appropriate to quantify the advice (for a $20 \%$ reduction compared to the last 3 years average official landings - 2010-2012).

There is a difference between the total landing statistics in the official data in this table and Table 17.2 with national landings (by country and gear type), for which not all data were available in 2013 and 2014.

Landings have been reported by the three countries with quota: France, Spain and Portugal. The respective time series, from 2001 to 2012, of national landings desegregated by gear are shown in Table 17.2.

This stock from is currently ranked as a Data Limited Stock in category 5.2; however, all the stocks covered by the current DCF sampling programme have been proposed to be upgrade to category 4 , because of the availability of biological information. Therefore, survey abundance indices, length frequency distributions, and other biological information is required from the respective National laboratories.
Length frequency distributions (LFD) were provided by IEO (Spain) for years 2011 and 2012 by metier. However, as Pollack is scarce in landings, most of samples ( $83 \%$ ) come from the gillnet fleet, due to it has a higher number of metiers than others fleets, as longline. Different mean sizes are obtained depending on the mesh size used (Figure XXX.2): 46.0 cm (GNS_DEF_60-79_0_0), 46.9 cm (GNS_DEF_80-99_0_0), and 48.8 cm (GNS_DEF_>=100_0_0).

Discards estimates of Pollack in Spanish trawlers were also provided by IEO (Spain) for year 1994, 1997, 1999, 2000, and the period 2003-2012. The low numbers of discards recorded makes it reasonable to assume that landings can be a proxy of catches.
Therefore, from the biological information compiled (scarce due to the low catches of this species in the area), just the LFD could be useful in order to improve the assessment of this stock in the future. However, the time series should be longer and more representative of the different metiers catching Pollack.

## 19 Whiting in Subarea VIII and Division IXa

Whiting (Merlangius merlangus) are caught in mixed demersal fisheries primarily by France and Spain (Table 19.1). Present fishery statistics are considered to be preliminary as there are concerns about the reliability of the French data from 2008-09. Landings may also contain misidentified Pollack (Pollachius pollachius). Whiting has never been recorded in Spanish discards and is negligible in Portuguese discards. However there are indications that there is considerable discarding by the French fleet.

This stock from is currently ranked as a Data Limited Stock in category 5.2 as there is information on landings only; however, all the stocks covered by the current DCF sampling programme have been proposed to be upgrade to category 4, because of the availability of biological information. For the first time this year national laboratories were requested via ICES Data call to provide information on quantity and length composition of commercial landings and discards (Table 19.2). Data were submitted by Spain, France and Belgium however as this is the first year these data must be considered preliminary. No information was received from Portugal. According to the French DCF National Programme and Technical reports, whiting in VIII have been sampled for age since 2011. These data may be useful to provide additional information on this stock.
Whiting are present in the French EVHOE-WIBTS-Q4 survey from the Bay of Biscay. Adults were not sufficient in number to serve as an SSB indicator but it may provide an index of recruitment. Commercial abundance index is available from Spanish pair trawl fleet in VIIIabd although it has declined to negligible levels in recent years.
This species is at the southern extent of its range in the Bay of Biscay and Iberian Peninsula (Figure 13.8.1). It is not clear whether this is a separate stock from a biological point of view.

## Annex 02 - Recommendations

| Recommendation | For follow up by: |
| :--- | :--- |
| The EWG notes that hake otoliths are currently collected but <br> not used in the assessment due to lack of a validated ageing <br> method. The EWG considers that ageing data would be | ICES Secretariat / ACOM |
| important to improve current hake assessment. The EWG also | WGBIOP, WGDATA |
| considers that it has no expertise on how this information could |  |
| be best obtained and, as a consequence, cannot provide |  |
| recommendation on the sampling level of hake otholiths. The |  |
| EWG recommends that WGBIOP and WGDATA look at these |  |
| issues. |  |
| The EWG notices that several of the new stocks assessed this | ACOM Leadership / |
| year have negligible catches and that there are distributed | WG on Stock Identification |
| mainly in more northerly areas. This includes the stocks of |  |
| Plaice (Pleuronectes platessa) in Subarea VIII and Division IXa |  |
| [ple-89a], whiting [whg-89a]and pollack [pol-89a]. The |  |
| scientific effort required to provide coverage of these less |  |
| abundant stocks in the southern area could be more useful if |  |
| applied to current stocks in the EWG. |  |
| A new index of abundance has been proposed and used for the <br> advice of sea bass in areas VIIIab. A similar index has been <br> estimated for the sea bass stock IVbc, VIIa,d-h. The EWG <br> recommends that the methodology be reviewed and <br> appropriateness for advice evaluated. |  |
| For the Iberian waters, several survey indices are used to <br> provide advice for several stocks of WGBIE. The EWG <br> recommends that the combination of those indices into one <br> combined index be assessed. | WGISDA |

## Annex 03: Term of Reference for 2016

WGBIE- Working Group for the Bay of Biscay and Iberic waters Ecoregion
2016/2/ACOM?? The Working Working Group for the Bay of Biscay and Iberic waters Ecoregion [WGBIE], chaired by ... , will meet in ... , 18-24 May 2016 to:
a ) Address generic ToRs for Regional and Species Working Groups (see table below);
b ) Assess the progress on the benchmark preparation of [???];
The assessments will be carried out on the basis of the stock annex in National Laboratories, prior to the meeting. The data to perform the assessment should be available 4 weeks before the meeting. This will be coordinated as indicated in the table below.

WGBIE will report by [?? May] for the attention of ACOM. The group will report on the ACOM guidelines on reopening procedure of the advice before 14 October and will report on reopened advice before 29 October.

## Annex 04: List of stock annexes

A list of stock annexes will be presented here (including direct hyperlinks) as soon as the work on the stock annexes is finalized.

Annex 05: Benchamark planning

| Stock | BSS-8ab |  |
| :--- | :--- | :--- |
| Stock coordina- <br> tor | Mickael Drogou | Mickael.drogou@ifremer.fr |
| Stock assessor | To define |  |
| Data contact | Mickael Drogou | Mickael.drogou@ifremer.fr |

| Issue | Problem/Aim | Work needed / <br> possible direction of solution | Data required. Are these available? Where should they come <br> from? |
| :--- | :--- | :--- | :--- |
| Landings data | Historical landings | Landings, fleet, area yearly required from 2000. | Landings from all the involved countries split by fleet, area |
| Tuning series | Commercial tuning data is <br> available. | Finalise the appropriate commercial tuning series including 2015. |  |
| Survey tuning <br> series | No survey tuning survey |  |  |
| Discards | Considered as negligible |  |  |
| Length <br> compositions | French length composition <br> from 2000 are not yet <br> available but should be in <br> 2015-2016 | Supply of length and age distributions for landings. This should include <br> sampling intensities. | French length and age distribution per year from 2000 per Ices area |

| Issue | Problem/Aim | Work needed / <br> possible direction of solution | Data required. Are these available? Where should they come <br> from? |
| :--- | :--- | :--- | :--- |
|  | Spain Length composition <br> would probably not be <br> available | Spanish Landings represents $3 \%$ of the total in 8ab. If not available <br> maybe not an issue |  |
| Biological <br> Parameters | No Biological Parameters <br> available in 2015, but some <br> data are currently <br> collected to have some <br> (maturity, growth curve <br> for nthe area) | Use some of the Biological data (Natural mortality) from the WGCSE <br> assesment. |  |
|  |  |  |  |

| Discards | Lack of discard data <br> from the French <br> fleets. since 1999. | Discard data from France since available data should be <br> provided. <br> Strengthening of the discards sampling is from 2009 on- <br> wards. <br> Before 2009, there is data, but it needs to be quality eval- <br> uated before use. | Data seems to be available at IFREMER. |
| Tuning se- <br> ries | France: No update of <br> LPUEs data series are <br> provided to the <br> group from 2008 on- <br> wards. | Provide LPUE data from France for different bottom <br> trawl fleet from 2008 onwards. | IFREMER to provide FU LPUE data series reviewed. |

| Issue | Problem/Aim | Work needed / <br> possible direction of solution | Data required. Are these available? Where should they come from? |
| :--- | :--- | :--- | :--- |
| Assessment <br> method | If the new discard <br> data are provided the <br> Bayesian sthatistical <br> catch at age model <br> should be updated <br> and fitted. | SCAA should be reviewed and updated to include new <br> discard data. With the new data, model priors should be <br> fitted. If it is approved by the benchmark, the absolute <br> values could be used as the basis for ICES advice. |  |
| Projections | SSB predicted by the <br> projection program is <br> not consistent with <br> the historical series <br> estimated by the <br> model | A revision of the projection program should be made and <br> its approval by the benchmark is needed to be used as the <br> basis for ICES advice. |  |
| Biological <br> Reference <br> Points | No defined | If new assessment success $\rightarrow$ they could be calculated us- <br> ing ICES EqSim program. |  |

## Annex 06. List of Working Documents

## WD 01 Irish Maturity Ogives 2004-2014

Hans Gerritsen
This document provides maturity-at-age estimates for stocks assessed by the WGCSE and WGBIE. All data are obtained on surveys and commercial sampling carried out by the Marine Institute.

## WD-02 Information from the Irish and French IBTS surveys to inform the assessment of monkfish in 78ab

## Hans Gerritsen

The French and Irish IBTS surveys appear to have good coverage of most of the distribution of Lophius spp. For L. piscatorius the first two age classes appear to be fully covered by the depth range of the surveys. It is not clear whether the full adult population is covered as considerably numbers may be present at depths greater than those covered by the surveys. It is possible to track cohorts in the length frequency distribution of both species, allowing growth parameters to be estimated. This, in turn, allows the length distribution to be split into age classes. The resulting numbers-at-age index shows good cohort tracking and internal consistency. If accurate catch or landings length-frequency data can be obtained, it may be possible to apply a similar length splits, using growth parameters estimated from the survey, which would allow an agebased assessment which can make use of the strong contrast between cohorts.

## WD-03 IEO scientific estimation of WGBIE stocks landings

José Castro
The methodology used to estimate Spanish landings had to be updated when processing the 2013 fisheries data due to changes in the quality and availability of fisheries statistics. WGBIE discussed and accepted this new methodology but requested a review of data from the previous two years (2011-2012) in order to facilitate comparison between both approaches. The 2013 data submitted last year were obtained with a preliminary version of the new methodology and therefore new landings estimations for the period 2011-2013 have been uploaded this year to InterCatch for northern and southern stocks of hake, anglerfishes and megrims. This working document describes both methodologies and provides an interpretation of their respective results.

WD-04 Review of the Spanish commercial tuning indices used in the assessment of the southern stocks of hake and anglerfish, and FU25 of Norway lobster

## J. Castro and R. Morlán

The largest Spanish commercial tuning indices in Atlantic Iberian waters are based on the bottom otter trawl fleet that operates from the port of A Coruña (Galicia, Spain). They are used by ICES in the assessment of a variety of Iberian demersal stocks, such as hake, anglerfish, megrims and Norway lobsters. However, the adaptation of scientific data bases to the recent update of raw fisheries statistics has caused irregularities in the submission of these tuning indices in the last five years. This paper provides the A Coruña commercial tuning indices for the southern stocks of hake, white anglerfish and black anglerfish, as well as Functional Unit 25 (West Galicia) of Norway lobster for 2009-2014.

## WD-05 Improved time-series of Hake catches per unit of effort for the Portugueses OTB fishery

João Pereira and Bernardo Alcoforado

During the 2010 benchmark, a new approach to the definition of a standardised hake CPUE time-series was proposed by Cardador and Jardim for the Portuguese commercial trawl fleet (as part of a Working Document). This methodology was defended and eventually approved to become part of the stock annex for the assessment of the species. It involved the analysis of vessel activity logs relating to individual vessel catches in weight by species, made within particular ICES rectangles over a specific number of hauls of a set duration. To this the main characteristics of each vessel (power, gross registered tonnage, length overall and type of license) were added in order to better characterise the catchability of fleet segments. The approved methodology was followed to produce a time-series used in the 2010 assessment with data up to 2009.Thereafter, several constraints made it impossible to update the series, which was nonetheless kept in the model. One of the main constraints was the introduction of a different data recording methodology used by the Fisheries Directorate General in Portugal, which relates to the gradual replacement of paper-based by electronic logbooks.In 2014, after the near complete implementation of electronic logbooks, a whole new time-series was reconstructed, which was then processed following the bechmark agreed methodology in order to obtain a new cpue time-series.

## WD-06 Langolf survey carried out from 2006 to 2014

Spyros Fifas et Michele Salaun
The WD (powerpoint presentation) summarise the results of the Langolf survey carried out in the Bay of Biscay from 2006 to 2014.

## WD-07 UWTV survey trial carried out on the Nephrops stocks of the Bay of Biscay

Spyros Fifas et Michele Salaun
The WD (powerpoint presentation) presents an exploratory Nephrops UWTV survey carried out in 2014 in the Bay of Biscay.

## WD-08 Estimation geostatistique de l'abondance de langoustine du Golfe de Gascogne par campagne de video sous-marine

Mathieu Woillez, Spyros Fifas et Michele Salaun
The WD (powerpoint presentation) presents a geostastistical analysis of the LAN-GOLF-TV carried out in the Bay od Biscay in 2014 to map and estimate the abundance of the Nephrops stock.

## WD-09 Improving stock assessment and managing bycatch rates using a multispecies approach. A case of study of the European Hake, Common and Bottlenose dolphins in Atlantic waters of the Iberian Peninsula

Camilo Saavedra, Santiago Cerviño and Simon Nothridge
Single-species models have been widely used to assess fish stocks; however, multispecies models offer a number of advantages over single-species models as a better appreciation of the fishing on ecosystem structure and function, and of the need to
consider the value of marine ecosystems for functions other than harvesting fish. The EU fishing policy demands that fisheries management moves toward an ecosystem approach, and ICES is seeking ways to ensure more integrated ways to present advice. In this working document a multispecies model is presented. Two species of cetaceans (Common and Bottlenose dolphins) were joined to the current Gadget model used for the assessment of the Southern European Hake. Dolphins act as predators of hake, since high consumption of hake and strong trophic interactions between these species were noted in previous studies. In this document we described the available data that were used to construct the model and the lack of good information to estimate some parameters were discussed. Special attention was placed on the estimation of the natural and bycatch mortality from strandings, trends in the abundance and proportions of prey consumed. Moreover, the possibility of assessing fisheries and marine mammals simultaneously was discussed. Cetacean bycatch mortality is fleet dependent and partial effort levels can be linked with a potential bycatch rate. Bycatch rates provided by observers on board are the best way to obtain accurate bycatch estimates of the fleet. However, since those are not currently available, our model might also provide a way to explore the feasibility of considering impacts of fishing on non-target species.

## WD-10 Nephrops (FU 30) UWTV Exploratory Survey on the Gulf of Cadiz Grounds

Yolanda Vila, , Burgos, C., Sobrino, I., Soriano, M., Barragán, C., Rueda, J.L., Gallardo, M., Farias, C. , Canoura, J. and Gil, J.

The WD presents an exploratory Nephrops UWTV survey carried out in 2014 on the Gulf of Cadiz fishing grounds by the Spanish Oceanographic Institute (IEO) within the framework of a project supported by Fundación Biodiversidad (Agricultura, Alimentación y Medio Ambiente Ministry) and European Fisheries Funds (EFF). The survey was designed from a multidisciplinary approach and the main objectives of the survey were: To set up the equipment and the UWTV survey methodology in the Gulf of Cadiz, obtain estimates of Nephrops burrows densities from a randomized isometric grid of UWTV stations spacing 5 nautical miles, obtain density estimates of macro benthos species and the occurrence of trawl marks on the sea bed, to collect sediment samples using a meso Box-Corer, to collect oceanographic data using a sledge mounted CTD

## WD-11 Stock definition of plaice and sole in 7hjk (WGCSE) and 89a (WGBIE)

Hans Gerritsen
Plaice and sole in 7 hjk and 89a are generally caught on distinct patches of sandy ground. It is not known how much exchange of eggs/larvae/fish there is between these patches. With the exception of sol-89a the landings are minor and result from bycatches in a mixed fishery. For these species areas 7hjk and 89a are at the edge of their distribution and their abundance in these areas is very low compared to their main distribution area.

WD 12 French Logbook data analysis 2000-2013: possible contribution to the discussion of the sea bass stock(s) structure/annual abundance indices.

## Alain Laurec and Mickael Drogou

Daily catch rates per vessel, grouped within months and ICES rectagles, have been analysed
basically through a multiplicative two factors model in order to estimate fishing powers and apparent abundances time series of sea bass within ICES rectangles. The abundance times series could potentially be used as an index of abundance for the stock assessment of sea bass.
