Abstract :

This study provides the length-weight relationship for eleven mesopelagic fishes from oceanic islands of the Southwestern Tropical Atlantic: Bonapartia pedaliota, Sigmops elongatus (Gonostomatidae), Argyropelecus aculeatus, Argyropelecus affinis, Argyropelecus sladeni, Sternoptyx diaphana, Sternoptyx pseudobscura (Sternoptychidae), Malacosteus niger, Thysanactis dentex (Stomiidae), Melanonus zugmayeri (Melanonidae), and Ectreposebastes imus (Setarchidae). Data were collected during a scientific survey (2017) around Rocas Atoll, Fernando de Noronha Archipelago and adjacent seamounts, using a micronekton trawl (side length of body mesh: 40 mm, side length of cod-end mesh: 10 mm) at 35 stations from 0 to 1,113 m depth. A new maximum standard length for Bonapartia pedaliota and Ectreposebastes imus are also provided.

INTRODUCTION

33   In the western Tropical Atlantic, the Fernando de Noronha Archipelago, Rocas
34   Atoll and adjacent seamounts host a remarkable biodiversity (Fiedler et al., 2016; Hazin
35   et al, 1998). For this reason, the marine ichthyofauna of this large biogeographic unit
36   categorized as Ecologically or Biologically Significant Marine Areas - EBSA (CBD,
37   2014) has been studied by many authors (Dominguez et al., 2016; Kikuchi &
38   Schobbenhaus, 2002; Oliveira et al., 2011). However, most efforts focused on fishes
39   living near to the surface (0-200 m) and few studies described the mesopelagic zone
40   (200-1000 m depth) of this region, which is considered as one of the most understudied
41   of the world ocean (St. John et al., 2016).

42   The mesopelagic community is a key resource for higher trophic levels,
43   maintaining part of the marine biodiversity and playing an important role in carbon
44   sequestration and thus on the biological carbon pump (Proud et al, 2017; St. John et al.,
45   2016). To better account for the role of this community in the ecosystem structure and
46   function, a prerequisite is to have the necessary biological information. One of such key
47   basic knowledge concerns the length-weight relationships (LWR) that are one of the
48   requisites for fisheries management and conservation (Froese, 2006; Froese et al.,
49   2011). Indeed, LWRs are used to estimate body weight by length measurements, assess
50   the condition factor or well-being of species of interest, as well as for the calculation of
51   production and biomass of a fish stock (Froese, 2006). Despite this, information on
52   LWRs are still lacking for many deep-sea fishes. Here, we provide new LWRs for
53   eleven mesopelagic fish species collected along the northeast Brazilian oceanic islands,
54   in order to increase the biological data and general knowledge of these species.

55   **MATERIAL AND METHODS**

56   The study area comprises the northeast Brazilian oceanic islands, including
57   Rocas Atoll (3°52'S, 33°49'W), Fernando de Noronha Archipelago (3°50'S, 32°25'W)
58   and adjacent seamounts. Data were collected during the scientific survey ABRACOS
59   (Acoustics along the BRAzilian COaSt) conducted on board the RV *Antea*, from 9th
60   April to 6th May 2017. Mesopelagic sampling was conducted using a micronekton trawl
61   (side length of body mesh: 40 mm, side length of cod-end mesh: 10 mm) at 35 stations
62   from 0 to 1113 m depth. After capture, the material was fixed in a 4% formalin solution
63   for one month and then preserved in a 70% alcohol solution for proximally six months
64   before processing for length and weight. At the laboratory, species were identified,

measured (nearest 0.1 cm of standard length, SL) and weighed (nearest 0.01 g of total weight, TW). All specimens were deposited in the Fish Collection of the Núcleo em Ecologia e Desenvolvimento Socioambiental de Macaé (NPM), Universidade Federal do Rio de Janeiro (NUPEM/UFRJ).

The parameters of the LWR were estimated through the equation: $TW = a \times SL^b$, where *TW* is the total weight (g), *SL* is the standard length (cm), *a* is a constant being the initial growth index and *b* is the slope of the regression. Prior to the calculation of LWRs, the relationship plots were executed for visual inspection and removal of outliers (Froese & Binohlan, 2000). The significance of the regression was tested by ANOVA and the degree of association between *TW* and *SL* was calculated by the determination coefficient (r^2). We only included LWRs for species with n > 30, except for three species for which a wide fish-length range was available.

RESULTS

A total of 11 species belonging to five families and three orders were analysed (Table 1). All regressions were highly significant (P < 0.01), with the coefficient of determination (r^2) ranging from 0.9511 to 0.9862. The value of *b* varied between 2.66 for *Sternoptyx pseudobscura* and 3.22 for *Sigmops elongatus*, while the parameter *a* ranged between 0.0012 for *Thysanactis dentex* and 0.0250 for *Ectreposebastes imus.*

DISCUSSION

This work provides the first LWR for six species: *S. pseudobscura*, *B. pedaliota*, *S. elongatus*, *T. dentex*, *M. zugmayeri*, and *E. imus*. LWR information has been previously available for *A. aculeatus, A. affinis*, *A. sladeni, S. diaphana*, and *M. niger*, but it was based on a small length range, small sample size (<5) and/or without the descriptive statistics of the relationships (Alpoim et al., 2002; Davison et al., 2015). All species presented here but *A. aculeatus* and *M. niger*, have no LWRs available in FishBase. In addition, the highest standard-length values for *Bonapartia pedaliota* and *Ectreposebastes imus* are reported herein.

As established by Froese (2006), the allometric coefficients for all LWRs were within the expected range of 2.5–3.5. These values are reflection of intrinsic characteristics and process of adaptations of each species, as ontogenetic reproductive or environmental variations, mainly between sexes (Froese, 2006). In addition, fixation

96   in alcohol and formaldehyde can affect length and weight measurements through the
97   shrinking and dehydration of specimens. For that reason, we recommend consider the
98   LWRs presented here as being tentative.

99   Overall, this study increases the knowledge on mesopelagic fishes, providing
100   basic biological information useful for further studies in ecology, conservation, and
101   fisheries assessment.
