Supplementary Methods

Thermodynamic calculations: reaction quotient calculation

The reaction quotient Q_r was calculated according to :

$$Q_r = \prod a_i^{V_{i,r}}$$

where a_i stands for the activity of the i^{th} species raised to its stoichiometric reaction coefficient $V_{i,r}$ in the r reaction. In the case of gases, activity is replaced by the fugacity f_i of the species.

The activity (a) of any species i can be determined according to:

$$a = \frac{C_i}{C_i^o} \times \gamma_i$$

where C_i stands for the concentration, C_i^o represents the standard state concentration (usually 1 m), and γ_i represents the corresponding activity coefficient (which is unitless).

The fugacity (f) of any i^{th} gas can be determined with the relation:

$$f_i = P_i \times \gamma_i$$

where P_i stands for the partial pressure (bar) and γ_i represents the corresponding fugacity coefficient (unitless).

Activity of H₂O (l) is taken to be unity ($a_{\text{H}_2\text{O}(l)} = 1$). Activity coefficients of bicarbonate ($\gamma_{\text{HCO}_3^-}$) and formate (γ_{HCOO^-}) are almost identical as they have the same species charge of -1 whatever the ionic strength and temperature as described by Amend et LaRowe (43). In our low-pressure condition (2 bar), regardless of the temperature or ionic strength, values of γ_i are 0.99–1.00. We therefore assumed that $f_i \approx P_i$.

Hence, calculation of reaction quotient (Q_r) for the reaction of CO₂ reduction to formate:

was simplified using concentrations considering activities of reactants and products almost equal to concentrations:

$$Q_r = \frac{a_{\text{HCOO}^-(\text{aq})} \times a_{\text{H}_2\text{O}(l)}}{f_{\text{H}_2(\text{g})} \times a_{\text{HCO}_3^-(\text{aq})}} = \frac{([\text{HCOO}^-] \times \gamma_{\text{HCOO}^-})}{(P_{\text{H}_2} \times \gamma_{\text{H}_2}) \times ([\text{HCO}_3^-] \times \gamma_{\text{HCO}_3^-})} \approx \frac{[\text{HCOO}^-]}{P_{\text{H}_2} \times [\text{HCO}_3^-]}$$

where $[i]$ represents the concentration of i in the aqueous solution (M) and P_i the partial pressure (bar).

Note that (Q_r) could also be calculated considering H₂ as dissolved. In that case, for uncharged species H₂, $\gamma_{\text{H}_2(\text{aq})} \approx 1$, regardless of temperature or ionic strength and thus, very little error is also introduced by equating $a_{\text{H}_2(\text{aq})} \approx [\text{H}_2]_{(\text{aq})}$.

Dissolved H₂ concentrations are estimated from the partial pressure of H₂ in the headspace (P_{H_2}) as described in Materials and Methods section.

Table S4. H₂ and formate concentrations used for representation of environmental concentrations measured for seawater and end-member fluids from six deep-sea hydrothermal vent fields in figure 6. At the pH used for the calculations (6.8), HCOOH was considered negligible as formic acid (pKa 3.75) does not significantly dissociate and remains at 99,999 % as HCOOH, and HCO₃⁻ represent the dominant form (>80%) of CO₂. The diversity of total CO₂ concentrations in endmember fluids at different hydrothermal sites were not specifically used for the thermodynamic modelling. (*) This work.

Figure S3. Comparison of the gene organisations of the *codh-nor* and *codh* clusters from 35 genomes of *Thermococcales*. Gene clusters of *Thermococcales* that perform H₂-dependent formate production are indicated in red. GenBank accession numbers are given in brackets. Data were obtained from SyntTax software (<http://archaea.u-psud.fr/synttax>).

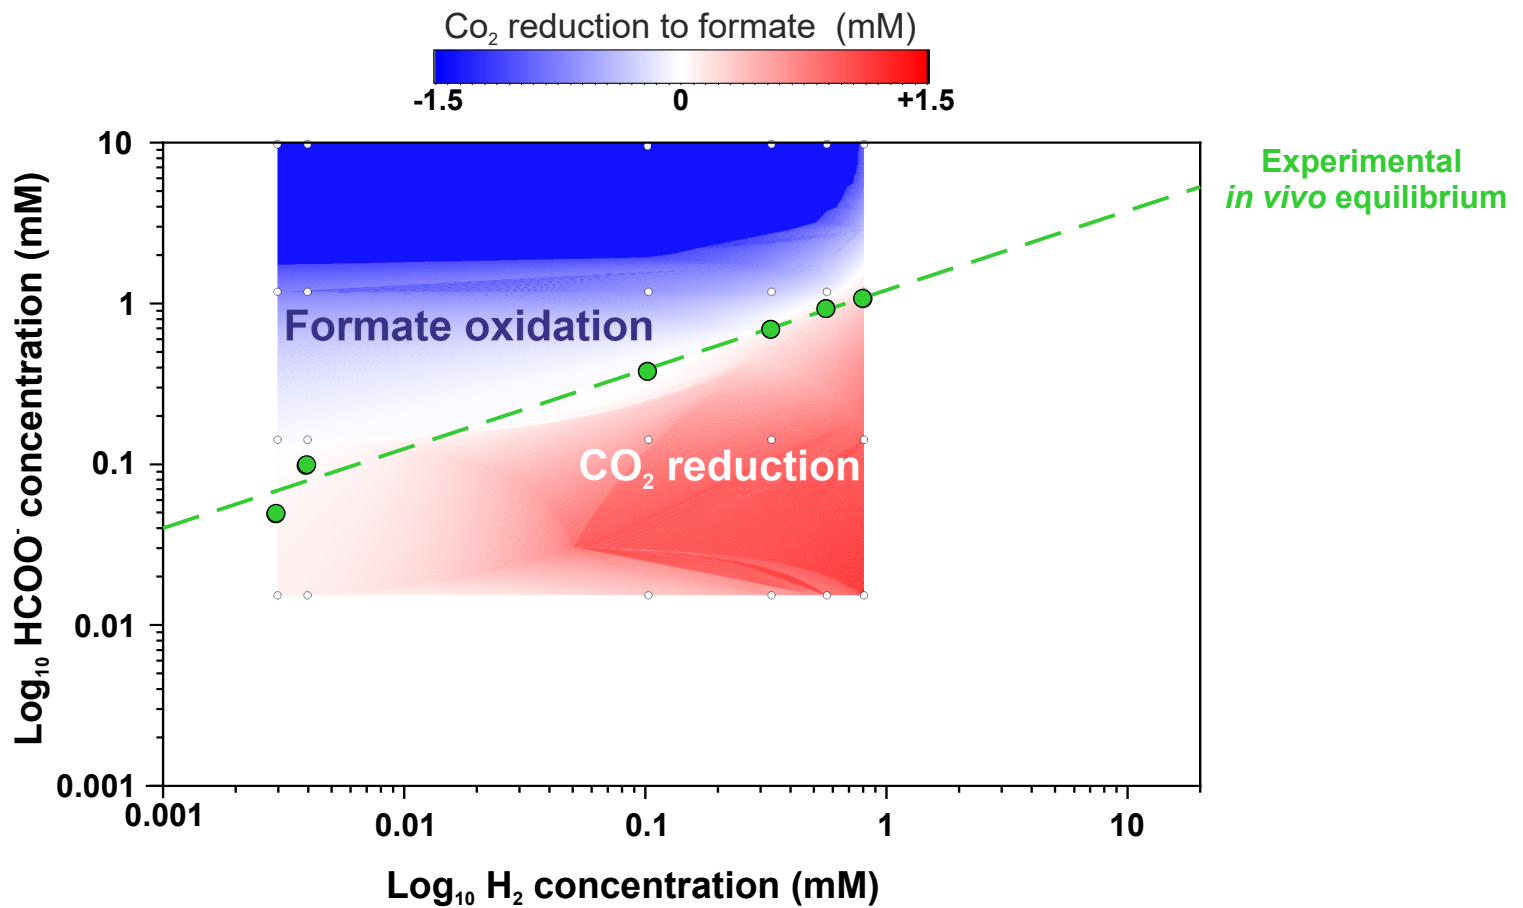

Figure S4. Cross effects of H₂ and formate on CO₂ reduction rate in *T. onnurineus* NA1 after 96 hours. The blue area indicates favourable zone for formate oxidation while the red area indicates favourable zone for CO₂ reduction and the white area when reaction is at equilibrium. Green dashed line defines the experimental *in vivo* point of chemical equilibrium of the reaction ($\Delta G' = 0 \text{ kJ mol}^{-1}$). Effect of H₂ concentrations was examined in a range of 0-80 % (v/v; 200 kPa; 0-0.8 mM dissolved H₂) with CO₂ concentrations kept at 20 % (v/v). Formate concentrations were in a range of 0 to 1 mM. ASW medium contained: 2 mM bicarbonate, 0.2 g L⁻¹ yeast extract, no S⁰ was added, temperature 80 °C.

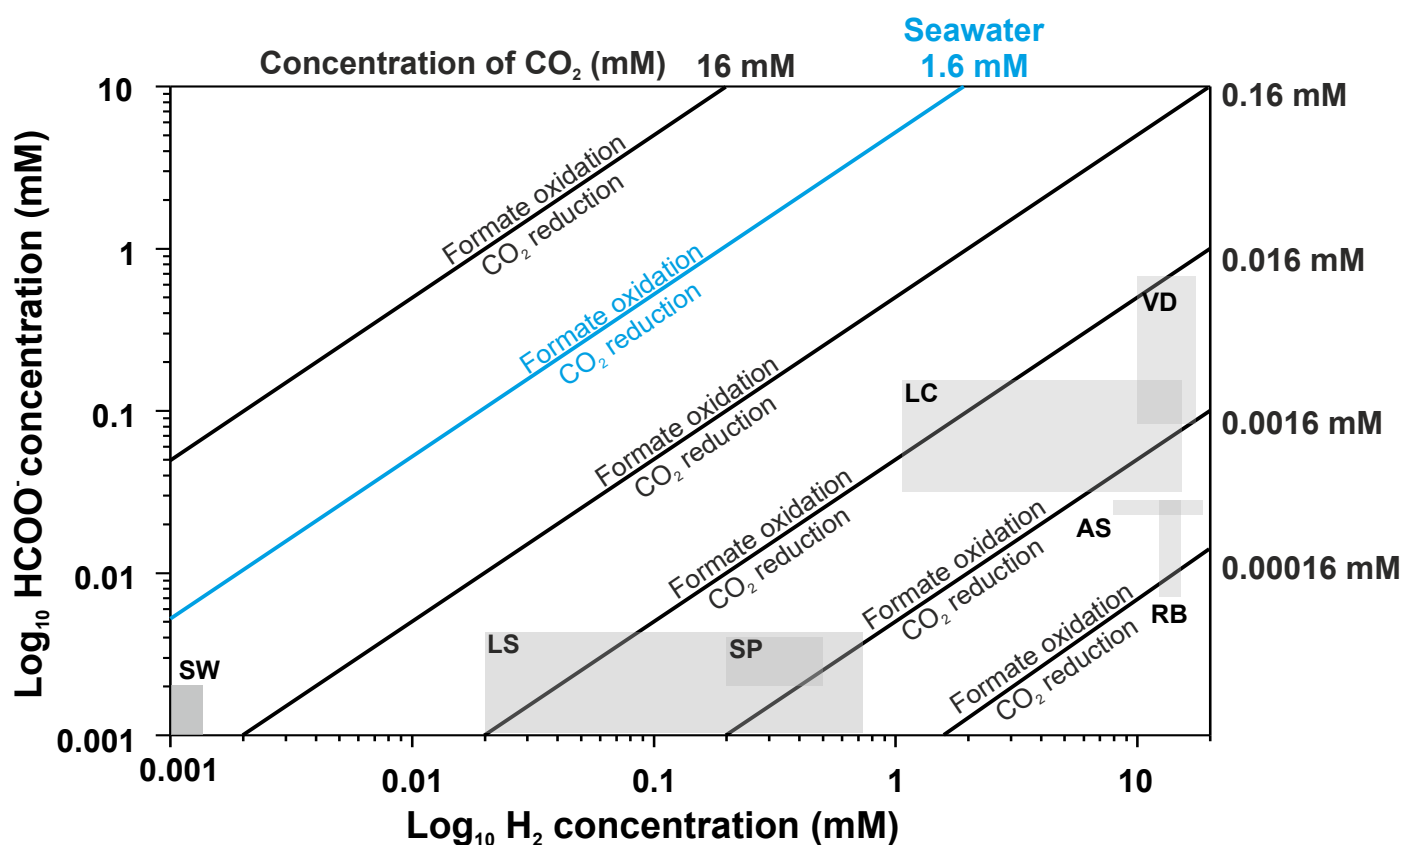

Figure S5. The direction of the reaction of CO₂ reduction depends primarily on substrates concentration. Plot representing the thermodynamic modelling of the CO₂ reduction to formate for a range of concentration of formate, H₂, and CO₂. Gibbs free energy of the reaction ($\text{H}_{2(\text{g})} + \text{HCO}_3^-_{(\text{aq})} \rightarrow \text{HCOO}^-_{(\text{aq})} + \text{H}_2\text{O}_{(\text{l})}$) was calculated for 80 °C and for a range of bicarbonate concentrations (0.00016 to 16 mM). 1.6 mM represents the bicarbonate concentration in seawater at a pH of 6.8 for a concentration of 2 mM total DIC. Black solid lines define points of chemical equilibrium of the reaction ($\Delta G' = 0 \text{ kJ mol}^{-1}$) from thermodynamic modelling for 6 different CO₂ concentrations, 0.00016 mM, 0.0016 mM, 0.016 mM, 0.16 mM, 1.6 mM, and 16 mM. Grey squares represent environmental concentrations measured for seawater and six hydrothermal vent field (data available on Table S4).

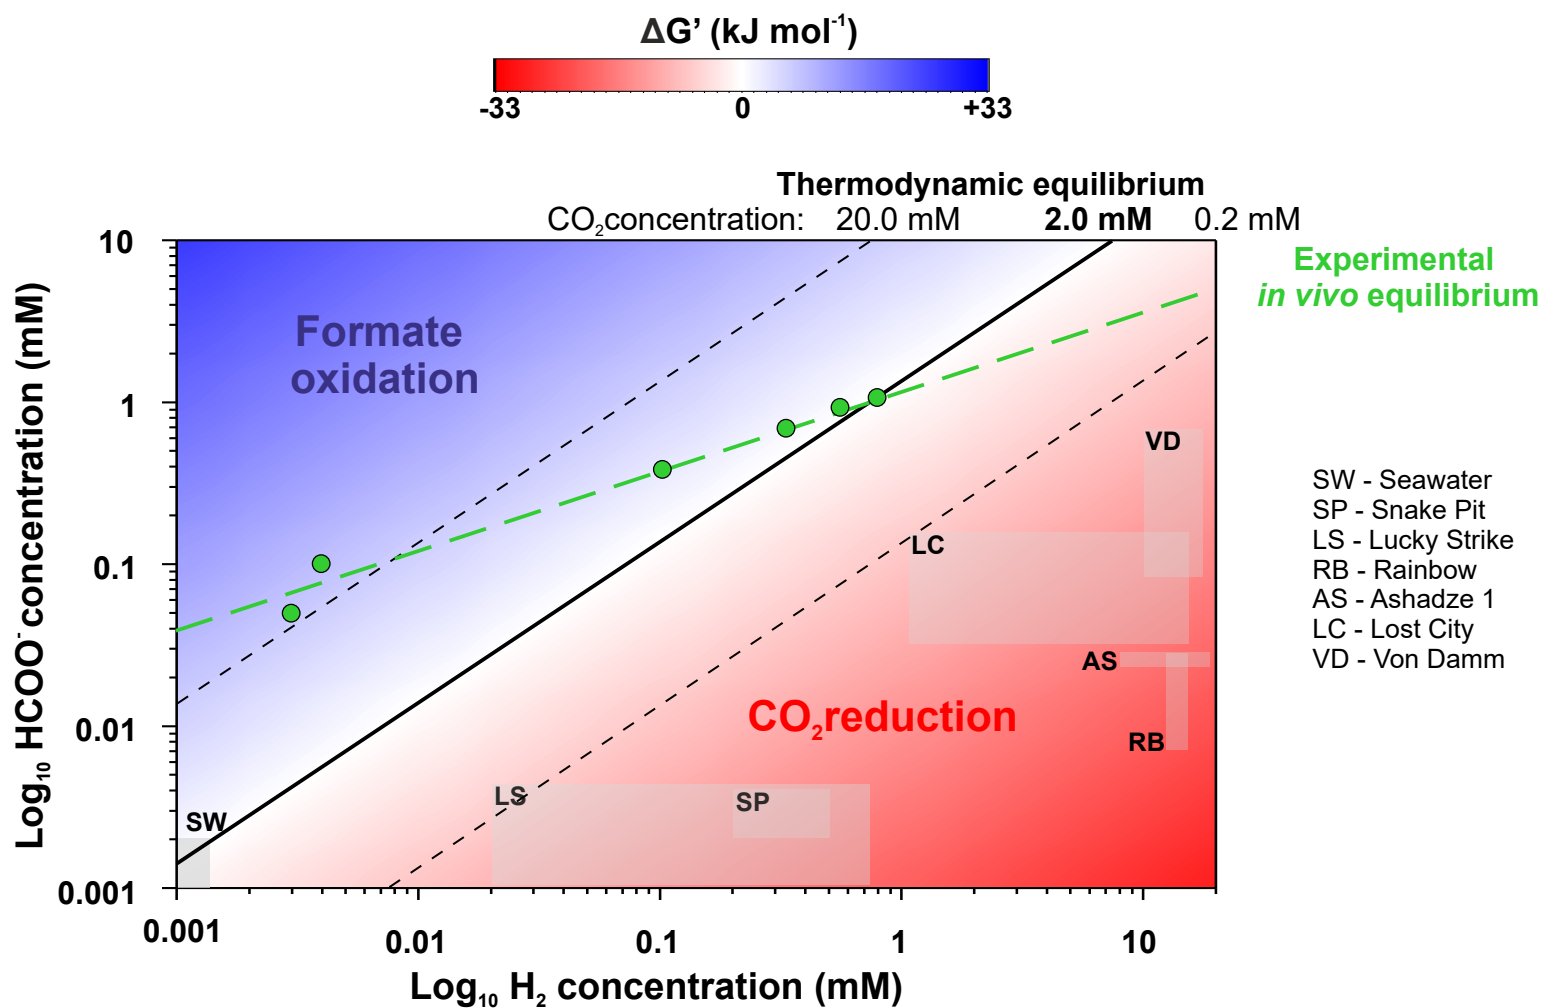

Figure S6. The direction of the reaction of CO₂ reduction depends primarily on substrates concentration. 2D-contour plot representing the thermodynamic modelling of the CO₂ reduction to formate for a range of concentration of formate and H₂. Gibbs free energy of the reaction ($\text{H}_{2(\text{aq})} + \text{HCO}_3^-_{(\text{aq})} \rightarrow \text{HCOO}^-_{(\text{aq})} + \text{H}_2\text{O}_{(\text{l})}$) was calculated for 80 °C and 2 mM of bicarbonate and H₂ was considered as dissolved. The blue area indicates conditions for which formate oxidation occurs while the red area indicates conditions for which CO₂ reduction to formate occurs. Black solid line and dashed lines define points of chemical equilibrium of the reaction ($\Delta G' = 0 \text{ kJ mol}^{-1}$) from thermodynamic modelling for three different bicarbonate concentration, 2.0 mM, 0.2 mM, 20.0 mM respectively. Green dashed line defines the experimental *in vivo* point of the chemical equilibrium of the reaction measured for *T. onnurineus* NA1 in culture medium after 96 hours of incubation at 80 °C (see details Fig. S4). Effect of H₂ concentrations were examined in a range of 0-80 % (v/v; 200 kPa; 0-0.8 mM dissolved H₂) with CO₂ concentrations kept at 20 % (v/v). Effect of formate concentrations were examined in a range of 0 to 1 mM. ASW medium contained: 2 mM bicarbonate, 0.2 g L⁻¹ yeast extract and no S⁰ was added. Grey squares represent environmental concentrations measured for seawater and six hydrothermal vent field (data available on Table S4).

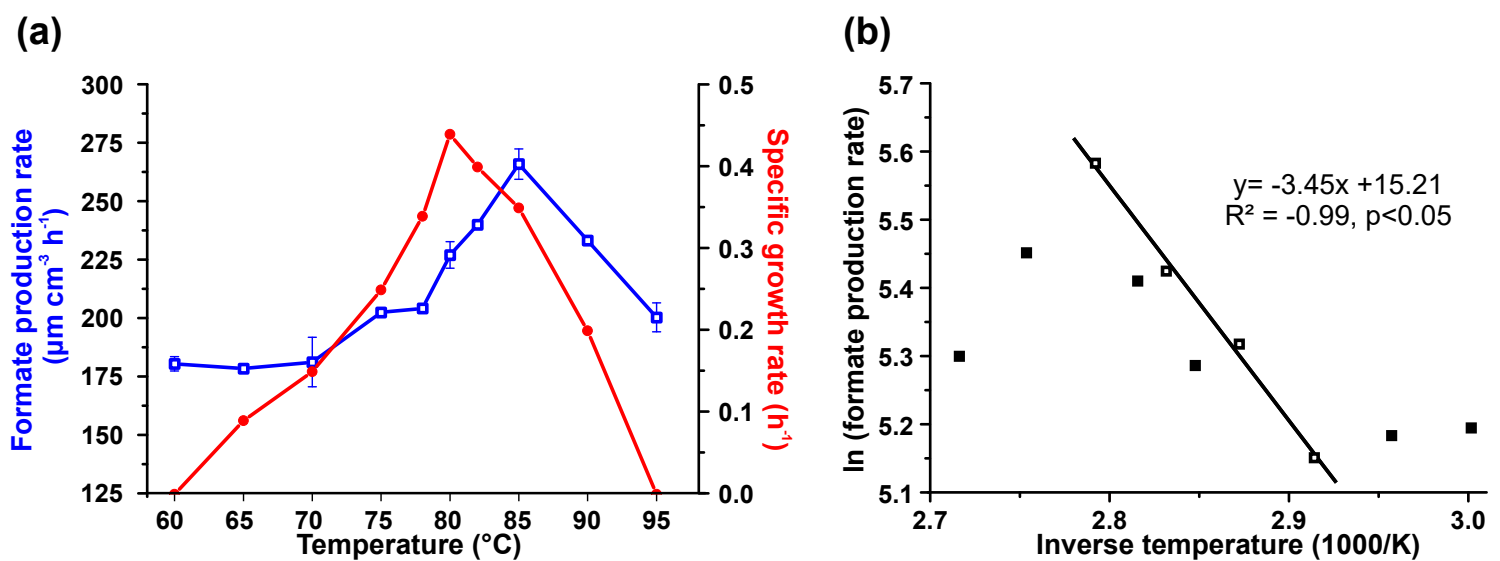

Figure S7. Effect of temperature on formate production rates in *T. onnurineus* NA1. **(a)** Formate production rates (blue squares) determined from the temperature-gradient incubation experiment after 24 hours of incubation and specific growth rate (red circles) obtained from (31). ASW medium contained: 30 mM bicarbonate, H₂/CO₂ (80:20, v/v; 200 kPa), and 0.2 g L⁻¹ yeast extract. Error bars show standard error (n = 3). **(b)** Arrhenius plot of the data from panel (a).
