Résumé. – Relations taille-poids chez 20 espèces de poissons de l'estuaire du Sine Saloum au Sénégal, en Afrique de l'Ouest.

Les relations tailles-poids (RTP) ont été estimées pour 20 espèces de poisson collectées au cours des missions de pêches scientifiques effectuées d'avril 1990 à octobre 2012 dans l'estuaire du Sine Saloum, Sénégal, avec comme engin de pêche la senne tournante coulissante et la senne de plage. Le nombre d'individus par espèce variait entre 10 (*Hemicaranx bicolor*) et 777 (*Carlarius latiscutatus*). La taille des poissons variait entre 4,5 cm de longueur totale (*Sphoeroides marmoratus*) et 130,0 cm de longueur totale (*Sphyraena afra*). Les valeurs du paramètre b de l'équation de la RTP [$W = aL^b$, où W est le poids (g) et L la taille (cm)] variaient de 2,687 (*Hemicaranx bicolor*) à 3,334 (*Citharichthys stampflii*). Le coefficient de détermination variait entre 0,953 (*Sphoeroides marmoratus*) et 0,996 (*Sphyraena afra*). La RTP n'a jamais été étudiée auparavant pour 13 espèces de poissons (*Carlarius parkii*, *Batrachoides liberiensis*, *Caranx senegallus*, *Hemicaranx bicolor*, *Trachinus terai*, *Elops senegalensis*, *Lutjanus goreensis*, *Citharichthys stampflii*, *Psettodes belcheri*, *Dagetichthys lusitanicus*, *Sphyraena afra*, *S. guachancho* et *Sphoeroides marmoratus*) dans l'estuaire du Sine Saloum. Cette étude fournit des informations sur les RTP qui n'existent pas encore dans FishBase (Froese et Pauly, 2020) pour 20 espèces (*Carlarius latiscutatus*, *C. parkii*, *Batrachoides liberiensis*, *Caranx senegallus*, *Hemicaranx bicolor*, *Cynoglossus senegalensis*, *Fontitrygon margarita*, *Plectorhinchus macrolepis*, *Pomadasys perotaei*, *Lutjanus goreensis*, *Citharichthys stampflii*, *Psettodes belcheri*, *Dagetichthys lusitanicus* et *Sphoeroides marmoratus*). Elle fournit aussi des gammes de taille qui ne sont pas spécifiées dans FishBase pour la relation taille-poids de 5 espèces (*Ephippion guttifer*, *Elops senegalensis*, *Pseudotolithus senegalensis*, *P. senegallus* et *Sphyraena afra*). En outre, de nouvelles tailles maximales sont présentées pour *Plectorhinchus macrolepis* et *Citharichthys stampflii*. Les paramètres obtenus à partir de cette étude étaient inédits pour certaines des espèces étudiées et ils seront utiles pour une bonne gestion des populations de poissons dans les pêcheries d'Afrique de l'Ouest.

Key words. – Length-weight relationship – Fish species – Saloum estuary – Senegal.

The relationship between length and weight of individuals in a fish population, with several other essential parameters, is a basic tool for fishery scientists, managers and biologists to assess the natural population dynamics (Le Cren, 1951; Froese, 2006). Fish length-weight relationships are useful in the estimation of biomass from length observations (Petrakis and Stergiou, 1995; Gonçalves *et al.*, 1997), fish population size (Dulčić and Kraljević, 1996;

Froese, 2006; Giarrizzo *et al.*, 2015) and growth patterns (Okgerman, 2005). They also provide useful information for fisheries biology and population dynamics (Sivashanthini, 2008) and stock assessment (Hampton, 2000; Fromentin and Fonteneau, 2001).

In this study, we assessed length-weight relationships for 20 species from the Sine Saloum estuary. This work complements those of Ecoutin and Albaret (2003) and Ndiaye *et al.* (2015) on some species in the Sine Saloum estuary. In addition, we have drawn up a table of LWRs of certain species whose LWRs have already been studied in the Sine Saloum estuary in order to observe differences, bearing in mind that our sampling methodology is not the same as that of Ndiaye *et al.* (2015).

MATERIALS AND METHODS

The Sine Saloum estuary is located 100 km south of Dakar, in Senegal, between 13°55' and 14°10' North and 16°03' and 16°50' West (Fig. 1). The Sine Saloum is an inverse estuary characterized by an increase in salinity in all seasons from 35 downstream up to 120 upstream (Diouf, 1996). The system comprises three main branches: from north to south, the Saloum, the Diomboss and the Bandiala, connected to each other by a vast network of small mangrove creeks locally named "bolong". Mangrove forests cover almost the entire southern portion of the system and progressively diminish in the north (Diouf, 1996; Simier *et al.*, 2004). Data were collected during scientific fishing surveys. The whole Sine Saloum estuary was sampled first from April 1990 to May 1993 (Diouf, 1996), with occasional samplings in 1994 and 1997, and then from 2002 to 2003 (Ecoutin *et al.*, 2010), with additional samplings from 2004 to 2007. The Bamboung bolong, a small tributary of the Diomboss, which has become a Marine Protected Area in 2004, was subject to a biological monitoring from 2003 to 2012 and the Sangako bolong, not far from the Bamboung Marine Protected Area but open to fishing, was also sampled for comparison from 2008 to 2012 (Ecoutin *et al.*, 2014; Sadio *et al.*, 2015).

Most sampling was carried out during the three main hydro-climatic seasons of the region, *i.e.* in March (end of the cool dry season), May-June (end of the hot dry season) and October (end of the wet season). The fish were caught using a purse seine (length 250 m, height 20 m, 14 mm mesh size; see Simier *et al.*, 2004) and a beach seine (180 m length, 9 m height and 25 mm mesh net; see Diouf, 1996).

Fish were identified to the species level and measured to the nearest mm (fork length for fish with a forked caudal fin with crescent or indented form; total length for species with a rounded cau-

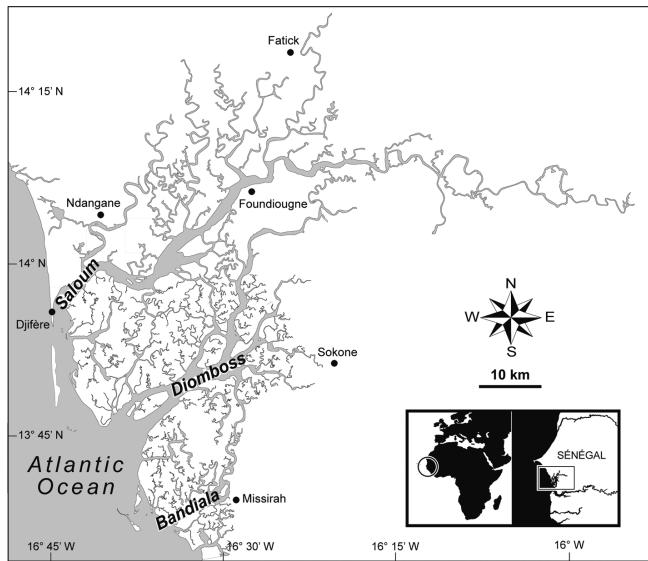

Figure 1. – Sampling site, Sine Saloum estuary.

dal fin with a pointed or truncated form; disc width for rays) and weighed to the nearest g. All data are available in PPEAO database (Simier *et al.*, 2019). Linear regressions of $\log(W)$ vs $\log(L)$, where W is total weight in g, L is total or fork length or disc width in cm were calculated to obtain the length-weight relationship of the form $W = aL^b$ (Froese, 2006) where $\log(a)$ is the intercept and b is the slope of the regression. Length and weight data were first plotted to identify outliers, the most extreme of which were finally excluded

from the analyses. Samples with $n < 10$ were excluded from the regression analyses.

RESULTS

Twenty fish species belonging to 14 families were considered in this study, making up 3293 individuals measured in the whole Sine Saloum estuary. Sample size, length and weight ranges, parameters of the LWR equations with 95% confidence limits and values of the determination coefficient r^2 were computed for the 20 species and reported in table I. The sample size for a given species varied from 10 (*Hemicaranx bicolor*) to 777 (*Carlarius latiscutatus*) individuals. Fish size ranged from 4.5 cm total length (*Sphoeroides marmoratus*) to 130 cm fork length (*Sphyraena afra*). The values of parameter b in the LWR equations varied from 2.687 (*Hemicaranx bicolor*) to 3.334 (*Citharichthys stampflii*). Linear regressions were significant for all species ($p < 0.001$) and provided suitable adjustments: the coefficient of determination (r^2) varied between 0.953 (*Sphoeroides marmoratus*, $n = 58$) and 0.996 (*Sphyraena afra*, $n = 68$). For 7 of the 20 species, LWRs have already been published for the Sine Saloum estuary (Tab. II) but with a smaller number of individuals (*Fontitrygon margarita*, *Plectorhinchus macrolepis*) or with a smaller size range (*Pseudotolithus senegalensis*) or with both a smaller number of individuals and a smaller size range (*Carlarius latiscutatus*, *Cynoglossus senegalensis*, *Pomadasys perotaei*, *Ephippion guttifer*). For the remaining 13 fish species, no information on LWRs was yet available in Senegal.

Table I. – Length-weight relationship (LWR) of 20 fish species from the Sine Saloum estuary in Senegal, from April 1990 to October 2012. Species: a, fork length; b, total length; c, disc width. Abbreviations: n, sample size; Max, maximum; Min, minimum; a and b, parameters of LWR; CL, confidence limits; r^2 , coefficient of determination.

DISCUSSION

The use of fishing gears with small mesh sizes (14 mm) allowed the sampling of a large range of sizes for most species, from juveniles to adults. The Sine Saloum estuary is known to be a nursery ground for juvenile fish (Vidy, 2000) and a spawning area (Diouf, 1996; Panfili *et al.*, 2004a, b, 2006; Diop *et al.*, 2017), what reflects the large size range of several species sampled.

This study provided LWRs that are so far not available in FishBase (Froese and Pauly, 2020) for *Carlarius latiscutatus*, *C. parkii*, *Batrachoides liberiensis*, *Caranx senegallus*, *Hemicaranx bicolor*, *Cynoglossus senegalensis*, *Fontitrygon margarita*, *Plectorhinchus macrolepis*, *Pomadasys perotaei*, *Lutjanus goreensis*, *Citharichthys stampflii*, *Psettodes belcheri*, *Dagetichthys lusitanicus* and *Sphoeroides marmoratus*. It also provided size ranges that are not specified so far for LWRs in FishBase for *Ephippion guttifer*, *Elops senegalensis*, *Pseudotolithus senegalensis*, *P. senegallus* and *Sphyraena afra*. In addition, new maximum total lengths are presented for *Plectorhinchus macrolepis* (53.8 cm vs 45.0 cm) and *Citharichthys stampflii* (17.5 cm vs 16.0 cm). For the 7 species already studied in the Sine Saloum estuary, the differences in the LWRs can be due to the difference in size range or number of individuals in the case of the species studied by Ecoutin and Albaret (2003). Sampling methods as well as season may affect the size of the fish collected either due to fishing gear selectivity or ontogenetic migration. More, sampling period may also impact fish weight due either to potential food availability (gut weight) or spawning period (gonad weight), as it could be the case for the species studied by Ndiaye *et al.* (2015). Thus, sampling periods as well as collection methods should be considered in LWR studies.

For all of the studied species in this study, the b values were generally in agreement with previous results by Froese (2006) *i.e.* b value comprised between 2.5 and 3.5. Also, it is well known that

the b value represents the body form, and is directly related to the weight affected by ecological factors such as temperature, food supply, spawning conditions and other factors (Ricker, 1973). Regression results suggest that the data from this study and the results presented here are reliable and can enrich Senegalese length-weight relationships in FishBase (Froese and Pauly, 2020). They will be useful tools to increase the ecological knowledge of these species in Sine Saloum estuary.

Acknowledgements. – The results presented here are from the multidisciplinary program linked to the projects Narou Heuleuk (FFEM/AFD/ONG Oceanium/IRD), AMPHORE (ANR Biodiversity) and Cepia (AFD/CSRP/UICN/IRD). The authors are grateful to the LEMAR team in Dakar and the fishermen and their team leader Mbaye Mbengue, also to the crew of the Diassanga research vessel and its captain François Sanseo, without whom these results could not have been obtained. The authors thank the two anonymous referee for their comments.
