Abstract :

The taxonomy of the extant dinoflagellate genus *Gonyaulax* is challenging since its thecate morphology is rather conservative. In contrast, cysts of *Gonyaulax* are varied in morphology and have been related with the fossil-based genera *Spiniferites* and *Impagidinium*. To better understand the systematics of *Gonyaulax* species, we performed germination experiments on cysts that can be identified as *S. ristingensis*, an unidentified *Spiniferites* with petaloid processes here described as *Spiniferites pseudodelicatus* sp. nov. and *Impagidinium variaseptum* from Chinese and Portuguese waters. Despite marked differences in cyst morphology, motile cells of *S. pseudodelicatus* and *I. variaseptum* are indistinguishable from *Gonyaulax baltica*. Motile cells hatched from *S. ristingensis* are morphologically similar to *G. baltica* as well but differ in the presence of one pronounced antapical spine. Three new

species, *Gonyaulax amoyensis* (cyst equivalent *S. pseudodelicatus*), *Gonyaulax bohaisensis* (cyst equivalent *I. variaseptum*) and *Gonyaulax portimonensis* (cyst equivalent *S. ristingensis*) were erected. In addition, a new ribotype (B) of *G. baltica* was reported from South Korea and a bloom of *G. baltica* ribotype B is reported from New Zealand. Molecular phylogeny based on LSU and SSU rRNA gene sequences revealed that *Gonyaulax* species with minute or short antapical spines formed a well resolved clade, whereas species with two pronounced antapical spines or lack of antapical spines formed the sister clade. Six strains of four above species were examined for yessotoxin production by liquid chromatography coupled with tandem mass spectrometry, and very low concentrations of yessotoxin were detected for one *G. bohaisensis* strain.

88 **INTRODUCTION**

This article is protected by copyright. All rights reserved

89 The fossil-based genus *Spiniferites* includes gonyaulacacean species with the Kofoidian thecal
90 plate tabulation Po, Cp, 4', 6'', 6c, 4–6s, 6''', 1p, 1'''' , and they usually have trifurcate gonal and/or
91 bifurcate intergonal processes, and a precingular archeopyle (Mertens and Carbonell-Moore 2018).
92 To date, 106 *Spiniferites* species are accepted (Williams et al. 2017) but only 13 of them are
93 known to be extant (Mertens and Carbonell-Moore 2018). Another fossil-based genus
94 *Impagidinium* is morphologically similar to *Spiniferites* but lacks tri- and/or bifurcate processes
95 (Stover and Evitt 1978). Several other fossil-based genera are morphologically similar to
96 *Spiniferites* as well. For instance, *Achomosphaera* only differs from *Spiniferites* in the lack of
97 sutural ridges (Evitt 1963); *Nematosphaeropsis* is distinguishable from *Spiniferites* because of the
98 presence of trabeculae connecting the distal ends of the processes (Deflandre and Cookson 1955).
99 Irrespective of the morphological dissimilarity among the fossil-based genera *Spiniferites*,
100 *Impagidinium* and *Nematosphaeropsis*, all of them gave rise to motile stages attributed to the cell-
101 based genus *Gonyaulax* Diesing (Lewis et al. 1999, Rochon et al. 2009, Mertens et al. 2018a). The
102 first equivalencies for the genus *Spiniferites* date back to the incubation of *Spiniferites bentorii* and
103 *S. mirabilis* from Woods Hole, MA, USA, which yielded cells identified as *Gonyaulax digitale*
104 and *G. spinifera*, respectively (Wall and Dale 1967). Currently, eleven *Spiniferites* species have
105 been related to *Gonyaulax* species, but several of them were attributed to *G. spinifera* (Dale 1983,
106 Rochon et al. 2009; Table S1 in the Supporting Information), highlighting the need to examine the
107 corresponding motile cells in detail using contemporary approaches.
108 To date, eleven extant *Impagidinium* species have been reported (Zorzi et al. 2019). Among
109 them, only *I. caspiense* has been related with *Gonyaulax baltica* (Mertens et al. 2018a),
110 although *G. baltica* has been related to *Spiniferites bulloideus* sensu as well (Ellegaard et al. 2002),
111 suggesting possible heterospory within Gonyaulacoid dinoflagellates (Mertens et al. 2018a).
112 *Gonyaulax* was erected to include *Gonyaulax spinifera* (Diesing 1866). The thecal plates of
113 *Gonyaulax* are often thick and ornamented by numerous reticulations to form ridges. Its plate
114 tabulation has been interpreted as Po, Cp, *4', 6'', 6c, ?s, 6''', 1p, 1'''' (Dodge 1989, Lewis et al.
115 1999, Carbonell-Moore and Mertens 2019), and now includes 77 recognized species (Gómez 2012,
116 Mertens et al. 2015, Lim et al. 2018, Gu et al. 2021). The thecate morphology of *Gonyaulax*

117 species is rather conservative and differs between species only in the cingular displacement and
118 overhang, the shape of the sixth precingular plate, the position of the ventral pore, the plate
119 ornamentation, the body size, the body shape and the number and size of antapical spines (Dodge
120 1989, Lim et al. 2018). Kofoid (1911) proposed to subdivide *Gonyaulax* into four subgenera (i.e.,
121 *Gonyaulax*, *Fusigonyaulax*, *Steiniella* and *Acanthogonyaulax* based upon the general shape of the
122 motile cells) but whether this is supported by molecular phylogenetics remains to be determined.
123 Several *Gonyaulax* species, identified as *Gonyaulax spinifera*, *G. membranacea*, and *G. taylorii*
124 are known to produce yessotoxins (YTXs), a marine polyether toxin (Rhodes et al. 2006, Riccardi
125 et al. 2009, Álvarez et al. 2016, Chikwililwa et al. 2019, Pitcher et al. 2019). Many strains have
126 been identified in the literature as *G. spinifera*, but likely belong to other *Gonyaulax* species. Other
127 *Gonyaulax* species (e.g., *G. whaseongensis*) are reported to be nontoxic (Gu et al. 2021), but the
128 number of species examined for YTX production is still limited.

129 To date, only two *Impagidinium* species (*I. caspiense* and *I. pallidum*) have sequences
130 available and *I. caspiense* groups together with *Spiniferites belerius* in molecular phylogenies,
131 whilst *I. pallidum* forms a separate clade (Mertens et al. 2018a, Gu et al. 2021). To better
132 understand the relationship between *Impagidinium* and *Spiniferites* we isolated single cysts of
133 *Impagidinium* and *Spiniferites* from surface sediments from Chinese, Zelanian and Portuguese
134 waters and performed germination experiments to obtain motile cells for SSU and LSU rRNA
135 gene sequence analyses. Both cyst and theca morphologies were examined in detail using LM and
136 SEM on selected strains, and molecular phylogeny was inferred based on LSU and SSU rRNA
137 gene sequences. In addition, several *Gonyaulax* strains were established from Korean and Zelanian
138 waters by isolating single cells and identified morphologically and by DNA sequences. Six strains
139 of four species (two strains of both *G. bohaisensis* sp. nov. and *G. portimonensis* sp. nov., and one
140 strain of each of *G. amoyensis* sp. nov. and *G. baltica*) were examined for YTX production by LC-
141 MS/MS.

142

143 **MATERIALS AND METHODS**

144 *Sample collection and treatment.*

145 Sediment sampling was done using an Ekman grab in Qinhuangdao (Bohai Sea) and Xiamen Bay
146 (East China Sea), China in 2018, and in Portimão, Portugal in Oct. 2019 using a Petite Ponar Grab
147 (Table 1). Samples were stored in the dark at 4°C until further treatment. Approximately 5 g of
148 wet sediment was mixed with 20 mL of filtered seawater and stirred vigorously to dislodge detrital
149 particles. The settled material was subsequently sieved through 120 µm and 10 µm mesh and
150 washed and collected with filtered seawater. The cyst fraction was separated from this residue
151 using sodium polytungstate at a density of 1.3 g · cm⁻³ (Bolch 1997). Single cysts morphologically
152 similar to *Impagidinium* and *Spiniferites* were isolated using a micropipette with an inverted
153 Eclipse TS100 (Nikon, Tokyo, Japan) microscope and incubated in small containers with f/2-Si
154 medium (Guillard and Ryther 1962) at 20°C, 90 µmol photons · m⁻² · s⁻¹ under a 12:12 h
155 light:dark cycle. Fifteen Chinese culture strains of *Gonyaulax* species were established
156 successfully (Table 1). Two Portuguese cultures were established, IFR-CC 20-019 and IFR-CC
157 20-018 in L1 culture medium.

158 Plankton samples were collected from the Korean coastal area using a 20 µm-mesh plankton
159 net. *Gonyaulax* species were isolated in laboratory using a capillary pipette with a light
160 microscope (Eclipse 50i; Nikon, Japan) and four strains of *Gonyaulax* species (LIMS-PS-3448,
161 LIMS-PS-3408, LMBE-HJ62 and LMBE-HJ86) were established successfully following the
162 methods described by Zhang et al. (2020).

163 Type specimens deposited in TIO; herbarium acronyms follow (Thiers 2022).

164

165 *Morphological study of thecate stages and cysts.*

166 Living cells and cysts of all strains or isolates listed in Table 1 were examined and photographed
167 using a Zeiss Axio Imager light microscope (Carl Zeiss, Göttingen, Germany) equipped with a
168 Zeiss AxioCam HRC digital camera. To observe the shape and location of the nucleus, cells were
169 stained with 1:100000 SYBR Green (Sigma Aldrich, St. Louis, MO, USA) for 1 min, and
170 photographed using the Zeiss fluorescence microscope with a Zeiss-filterset (excitation BP470/40,
171 beam splitter FT495, emission BP525/50). Cell and cyst size was measured based on LM images.
172 Portuguese and Korean strains were photographed and measured using an Olympus DP72 camera

173 mounted on a BX41 microscope with 1009 oil immersion objectives and a Nikon DS-Ri2 camera
174 mounted on a ECLIPSE Nikon microscope, respectively.

175 For SEM, mid-exponential batch cultures of selected Chinese strains were concentrated by a
176 Universal 320 R centrifuge (Hettich-Zentrifugen, Tuttlingen, Germany) following standard
177 protocols (Gu et al. 2021) and examined with a Zeiss Sigma FE (Carl Zeiss, Oberkochen,
178 Germany) SEM at Xiamen University, China.

179 For SEM observations of Portuguese strains, cells were picked from microwells using a IX70
180 (Olympus) inverted microscope and filtered using polycarbonate membrane filters (0.22 µm pore
181 size, GTTP Isopore, Millipore, Billerica, MA, USA), and filters were processed according to the
182 methods described in Chomérat and Couté (2008). They were dehydrated in a graded series of
183 ethanol baths (15–100%), critical-point-dried, sputter coated with gold. Cells on the stubs were
184 examined at the Station of Marine Biology in Concarneau using a Sigma 300 Gemini (Zeiss,
185 Oberkochen, Germany) field-emission SEM equipped with both a conventional Everhart-
186 Thornley and in-lens secondary electron detectors, operated at 5 kV.

187 For SEM observations of Korean strains, 2 mL of mid-exponential batch cultures of strains
188 were fixed by Lugol's Iodine solution (0.1% final concentration) for 24 h at room temperature,
189 then rinsed by centrifugation with deionized water. After rinsing, samples were dehydrated,
190 critical point dried and examined following standard protocols (Zhang et al. 2020). Tabulation
191 labeling follows the Kofoid system (Kofoid 1911). The sulcal plate labeling follows Balech
192 (1980).

193
194 *PCR amplifications and sequencing.*

195 Single cells of Chinese strains were isolated and washed several times with sterile distilled water.
196 They were broken by applying gentle force on the coverslip with the inverted microscope and
197 pipetted into a PCR tube for templates. Various regions of rRNA genes including the SSU, partial
198 LSU (D1–D6) and ITS1–5.8S–ITS2 were amplified using primer pairs specified previously and
199 following standard protocols (Luo et al. 2019).

200 For Korean strains, genomic DNA was extracted from 1 mL of exponentially growing cultures

201 using the DNeasy Plant Mini Kit (QIAGEN Inc., Valencia, CA, USA) following the
202 manufacturer's instructions. The SSU, ITS1-5.8S-ITS2 and LSU rDNA sequence were amplified
203 using the primer pairs SR1 and SR12b, SSUITS and 25R1, and 25F1 and R2 (Yamaguchi and
204 Horiguchi 2005, Takano and Horiguchi 2006) following standard protocols (Zhang et al. 2020).
205 For Portuguese strains, genomic DNA was extracted from 20 µL of exponentially growing
206 cultures using the PCR BIO Rapid extract PCR kit (PCR Biosystems Ltd, London, UK) following
207 the manufacturer's instructions. Almost the full length of the SSU rDNA was specifically
208 amplified using primers 18S-FW and 18S-RV and for the ITS1-5.8S-ITS2-LSU rDNA, an
209 amplicon of more than 1300 bp was obtained with primers ITS-Fw and D3B (Nézan et al. 2012)
210 following standard protocols (Gu et al. 2021). For the New Zealand strain, genomic DNA
211 extraction, PCR and sequencing conditions for the LSU rRNA were performed as described in
212 Smith et al. (2016). Newly obtained sequences were deposited in GenBank with accession
213 numbers OM177644 to OM177653 and OM228714 to OM228731.

214

215 *Sequence alignment and phylogenetic analysis.*

216 Newly obtained LSU rRNA (ca. 1300 bp) and SSU rRNA (ca. 1700 bp) gene sequences were
217 aligned with sequences of *Gonyaulax* species and related taxa available in GenBank. Sequences
218 were aligned using MAFFT v7.110 (Katoh and Standley 2013) online program
219 (<http://mafft.cbrc.jp/alignment/server/>) with default settings. Alignments were manually checked
220 with BioEdit v7.0.5 (Hall 1999). The final alignment consisted of 1527 LSU and 1841 SSU base
221 pairs including introduced gaps. For Bayesian inference (BI), the program jModelTest (Posada
222 2008) was used to select the most appropriate model of molecular evolution with Akaike
223 Information Criterion (AIC). Bayesian reconstruction of the data matrix was performed using
224 MrBayes 3.2 (Ronquist and Huelsenbeck 2003) with the best-fitting substitution model (GTR+G).
225 Four Markov chain Monte Carlo (MCMC) chains ran for 2,000,000 generations, sampling every
226 1000 generations. The first 10% of burn-in trees were discarded. A majority rule consensus tree
227 was created to examine the posterior probabilities (PP) of each clade. Maximum likelihood (ML)
228 analyses were conducted with RaxML v7.2.6 (Stamatakis 2006) on the T-REX web server (Boc et

229 al. 2012) using the model GTR+G. Bootstrap support (BS) was assessed with 1000 replicates.

230

231 *Yessotoxin analysis.*

232 Cultures of six strains (TIO726, TIO732, TIO711, IFR20-018, IFR20-019, and CAWD374) were
233 grown in 200 mL Erlenmeyer flasks under standard culture conditions. At the stationary phase
234 (determined using sequential cell counts), $\sim 10^5$ – 10^6 cells were concentrated by a Universal 320 R
235 centrifuge (Hettich-Zentrifugen, Tuttlingen, Germany) at 2500g for 10 min at 4°C. Cell pellets for
236 quantification of intracellular YTX were transferred to 2 mL microcentrifuge tubes and stored at -
237 20°C until analysis. Measurements were carried out by liquid chromatography (LC 1100, Agilent,
238 Waldbronn Germany) coupled to tandem mass spectrometry (API 4000 QTrap, Sciex, Darmstadt
239 Germany) as detailed in Wang et al. (2019). Yessotoxins were screened in the negative mode by
240 selected reaction monitoring (SRM). Screened YTX variants and their respective mass transitions
241 are given in supplemental materials (Table S2 in the Supporting Information).

242 For strains TIO732, IFR20-019 and IFR20-018, sample analyses were performed by LC–
243 MS/MS using a Shimadzu UFLCxR system coupled to a triple quadrupole hybrid mass spectrometer
244 Q-Trap (API400QTrap, Sciex) equipped with a heated electrospray ionization (ESI) source. Data
245 acquisitions were performed in negative ion mode and using MRM (Multiple Reaction Monitoring)
246 mode. Chromatographic separation was carried out on a reversed-phase column Xbridge BEH C18
247 (50×2.1 mm, 2.5 μ m, Waters) equipped with a guard column (5×2.1 mm, 2.5 μ m, same
248 stationary phase as column). Water (A) and acetonitrile 90% (B) both containing 6.7 mM of
249 ammonium hydroxide were used as mobile phases at a flow rate of 400 μ L \cdot min⁻¹. The following
250 gradient was used: 0 min, 5% B; 1.5 min, 5% B; 4.5 min, 65% B; 5.0 min, 100% B; 7.0 min, 100%
251 B; 7.5 min, 5% B; 12.0 min, 5% B. The oven temperature was 30°C and the injection volume was
252 5 μ L. The LC–MS/MS method was used to detect 13 toxins (Table S3 in the Supporting
253 Information). Quantification was performed relative to YTX and homo-YTX standards (National
254 Research Council Canada) with a 6-point calibration curve. The limit of quantification was 0.03
255 ng \cdot mL⁻¹ for YTX and homo YTX standards. The ESI interface operated using the parameters
256 described in Wang et al. (2019).

257

258 **RESULTS**

259 In this study, 22 strains of *Gonyaulax* were established and identified based on the morphology of
260 both cysts and thecae, and confirmed by DNA sequences. Nine strains were identified as *G.*
261 *bohaiensis* sp. nov. (cyst equivalent *Impagidinium variaseptum*), seven strains as *G. amoyensis* sp.
262 nov. (cyst equivalent *S. pseudodelicatus*), two strains as *G. portimonensis* sp. nov. (cyst equivalent
263 *S. ristingensis*) and four strains as *G. baltica* (Table 1). *Gonyaulax baltica* from the Pacific proved
264 to be genetically separated from those in the Atlantic and formed a new ribotype. Only one strain
265 of *G. bohaiensis* was tested positive for YTX production.

266

267 ***Gonyaulax bohaiensis* H.Gu, K.N.Mertens & H.H.Shin sp. nov. (Figs. 1, 2, S1–S3 in the**
268 **Supporting Information)**

269 *Description:* Cells were 25–46 μm long and 21–37 μm wide with numerous minute antapical
270 spines. The epitheca was conical with intermediate shoulders. The cell surface was thick and
271 reticulated. Small pores were scattered over the thecal plates, and were aligned along the cingulum.
272 The sulcal plates bear neither pores nor reticulation. The torsion was neutral. The cingulum was
273 located in the equatorial part of the cell and descended with a displacement and overhang of about
274 2.5 times its width. Sexiform hypothecal configuration. Cells displayed a plate formula of Po, Cp,
275 4', 6'', 6C, 6S, 5''', 1p, 1'''''. Plate 6'' was very elongated. A ventral pore was located at the junction
276 of plates 1', 4'a and 4'p. The angle between the major axis and a line joining the ends of the
277 cingulum was approximately 35–45°. The cyst was subspherical to ellipsoidal, 36–41 μm long and
278 30–36 μm wide with an apical boss (excluding the crests). The cyst had low sutural septa 2.0–4.8
279 μm high, except around the antapical plate where the septa were 4.0–7.6 μm high. The cyst
280 displayed a paratabulation of 4', 6'', 6C, 6S, 5''', 1p, 1'''''. The paracingulum descended with a
281 displacement of two-three times its width. The archeopyle was reduced and corresponded to plate
282 3''.

283 *Holotype* (designated here): TIO 202201, SEM stub of thecate cells from a culture established
284 from a cyst extracted from surface sediment of Bohai Sea, June 14, 2018, collected by Haifeng Gu.

285 *Type locality*. Bohai Sea; 39°56.34' N, 119°44.74' E.

286 *Habitat*. Marine and planktonic with benthic cyst stage.

287 *Etymology*. The epithet '*bohaiensis*' is derived from Bohai Sea and refers to the type locality.

288 *GenBank accession numbers*. OM177646 (SSU), OM228722 (LSU)

289 *Remarks*. The morphology of the cyst resembles the fossil based taxon *Impagidinium*
290 *variaseptum* (see discussion).

291 *Morphology*. Cysts of *Gonyaulax bohaiensis* had a subspherical to ellipsoidal central body with
292 one pronounced yellow-orange accumulation body, many transparent lipid bodies and a spherical
293 nucleus (Figs. 1A, S1A). They were 36.0–40.5 μm in length (mean = $37.9 \pm 1.4 \mu\text{m}$, n=8) and
294 30.0–36.0 μm in width (mean = $33.5 \pm 1.9 \mu\text{m}$, n=8). The central body wall was formed of pedium
295 and tegillum. The pedium was smooth, and the tegillum was microgranulate and formed the
296 parasutural crests. The height of the parasutural septa was 2.0–4.8 μm (mean = $3.5 \pm 1.1 \mu\text{m}$, n=8),
297 except around the antapical paraplate where the septa were higher (4.0–7.6 μm , mean = 5.9 ± 1.2
298 μm , n = 6, Fig. 1, A and C). The septa could form short, exclusively gonial processes which can
299 have minute furcations. The epicyst had a smooth rounded apex with an apical boss (Fig. 1, B, C
300 and F). There was a ventral pore at the junction of plates 1', 4'a and 4'p (Fig. 1B). The parasutures
301 between 1' and 4' were faintly visible. Plate 6'' was very elongated. The paracingulum descended
302 with a displacement of two to three cingular widths (Fig. 1, B and F). The parasulcal plates were
303 sometimes faintly discernable. The torsion was neutral (Fig. 1D). The archeopyle was precingular
304 and reduced corresponding to paraplate 3'' (Fig. 1D). The operculum was monoplacate and free
305 (Fig. S1B). Cysts of *G. bohaiensis* were commonly found in Bohai Sea.

306 Cells of *Gonyaulax bohaiensis* strain TIO726 were 25.3–45.6 μm (mean = $31.3 \pm 3.7 \mu\text{m}$, n=52)
307 long and 21.1–37.0 μm (mean = $26.0 \pm 3.4 \mu\text{m}$, n=52) wide. Cells had a conical epitheca with
308 intermediate shoulders and a rounded hypotheca (Fig. 2, A and B). There were numerous bean-

309 shaped chloroplasts located in the periphery of the cell (Fig. S1, C and D). The nucleus was
310 elongated and curved, extending from the left epicone to the right hypocone (Fig. S1, D and E).
311 The thecae had a sexiform gonyaulacoid tabulation in the hypotheca (sensu Fensome et al.,
312 1993, their text-fig. 64B) with a S-type ventral organization (sensu Fensome et al. 1993, text- figs.
313 82, B and D) and neutral torsion (sensu Fensome et al. 1993, text-fig. 83B; Fig. 2, A–D).
314 The pore plate was lanceolate in shape and surrounded by raised ridges of neighboring apical
315 plates (Fig. 2D). The first and fourth apical plates (1', 4') were small and narrow (Fig. 2, B and C).
316 A ventral pore was observed at the junction of plates 1', 4'a (anterior part of 4') and 4'p (posterior
317 part of 4', Figs. 2D, S1F). The plate 6'' was triangular (Fig. 2A). The cingulum descended with a
318 displacement of around 2.5 widths (Fig. 2A) and an overhang also around 2.5 widths (Fig. 2E).
319 All postcingular plates were similar in size. Plate 1p was located adjacent to plates Sp and Ssp
320 (Fig. 2F). Plate 1''' was located in the middle of the hypotheca with numerous short spines
321 approximately 1.0 µm long (Fig. 2F). The sulcus was narrow in the middle but wide at both ends.
322 It was comprised of the anterior sulcal plate (Sa), the anterior left sulcal (Ssa) plate, the posterior
323 left sulcal (Ssp), the right anterior sulcal plate (Sda) and right posterior sulcal plate (Sdp) and
324 posterior sulcal plates (Sp; Fig. 2, F and G). A schematic plate pattern is provided in Figure S2.
325 Cells of the Korea strain LIMS-PS-3448 were morphologically similar to the Chinese strains, but
326 differed in possessing several medium-sized antapical spines (Fig. S3, A–E). Plates 3'' and *4'''
327 were identified as the keystone plates (Fig. S3, D and E).

328

329 ***Gonyaulax amoyensis* H.Gu & K.N.Mertens sp. nov.** (Figs. 3, 4, Figs. S4, S5 in the Supporting
330 Information)

331 *Description.* Cells were 24–42 µm long and 19–29 µm wide with numerous minute antapical
332 spines. The epitheca was conical with short shoulders. The cell surface was thick and reticulated.
333 The cingulum was located in the equatorial part of the cell and descended with a displacement and
334 overhang of around 2.5 widths. Cells displayed a plate formula of Po, Cp, 4', 6'', 6C, 6S, 5''', 1p,
335 1'''. A ventral pore was present at the junction of plates 1', 4'a and 4'p. The angle between the
336 major axis and a line joining the ends of the cingulum was approximately 25–35°. The cyst was

337 ovoid to ellipsoidal, 29–40 μm long and 26–36 μm wide with a low apical boss. They were
338 ornamented with gonal (occasional intergonal), petaloid processes 6–13 μm long, and connected
339 by low to high membranous flanges. The paracingulum descended with a displacement of two to
340 three times its width. The archeopyle was reduced and corresponded to plate 3''.

341 *Holotype* (designated here). TIO 202202, SEM stub of thecate cells from a culture established
342 from a cyst extracted from surface sediment of East China Sea on February 27, 2018, collected by
343 Haifeng Gu.

344 *Type locality*. East China Sea; 24°35.57' N, 118°9.20' E.

345 *Habitat*. Marine and planktonic with benthic cyst stage.

346 *Etymology*. The epithet '*amoyensis*' is derived from Amoy, the old English name based on the
347 Hokkien pronunciation of Xiamen, and refers to the type locality.

348 *GenBank accession numbers*. OM177649 (SSU), OM228717(LSU).

349 *Remarks*. The geological preservability of these cysts was demonstrated by their ability to
350 withstand palynological treatment. The cyst resembles the fossil-based taxon *Spiniferites*
351 *pseudodelicatus* described below.

352

353 ***Spiniferites pseudodelicatus* K.N.Mertens, H.Gu sp. nov.** (Fig. 3C)

354 *Description*. The cyst was subspherical to ellipsoidal, 36–41 μm long and 30–36 μm wide with
355 an apical boss (excluding the crests). The cyst had sutural septa 2–5 μm high, except around the
356 antapical plate where the septa were 4–8 μm high. The cyst had a tabulation of 4', 6'', 6C, 6S, 5''',
357 1p, 1'''''. The paracingulum descended with a displacement of two-three times its width. The
358 archeopyle was reduced and corresponded to plate 3''.

359 *Holotype* (designated here): FR CEDiT2022H137, SEM stub from a cyst isolated from surface
360 sediment collected on May 26, 2008, by Dong Xu. Dinoflagellate type collection in the Centre
361 of Excellence for Dinophyte Taxonomy (CEDiT, Wilhelmshaven, Germany).

362 *Type locality*. South China Sea (21°19.80' N, 111°10.20' E, 17.5 m water depth).

363 *Habitat.* Marine.

364 *Etymology.* The epithet '*pseudodelicatus*' was chosen because of the superficial morphological
365 similarity of the cyst to *Spiniferites delicatus*.

366 *Morphology.* Cysts of *Gonyaulax amoyensis* had an ovoid to ellipsoidal central body, and were
367 28.7–39.6 μm (mean = $32.2 \pm 3.9 \mu\text{m}$, n=6) long and 26.2–35.6 μm (mean = $29.9 \pm 3.1 \mu\text{m}$, n=6)
368 wide. The central body wall was formed of pedium and tegillum. The pedium was smooth, and the
369 tegillum was microgranulate and formed the parasutural crests. They were ornamented with
370 processes 5.6–12.9 μm long (mean = 7.9 ± 1.9 , n=21), and connected by low to mid-high
371 membraneous flanges (Fig. 3A). The paracingulum descended with two-three times of its widths
372 (Figs. 3C, S4A). The cyst wall was 0.8–1.2 μm thick (mean = $1.1 \pm 0.2 \mu\text{m}$, n=5). The processes
373 were gonial, wide, petaloid and trumpet-shaped with multifurcated tips (Fig. 3, C and D).

374 Occasionally an intergonal process was observed in the postcingular paraseries, which did not
375 show furcated tips (Fig. 3A). A low apical boss was observed (Fig. 3C). The archeopyle was
376 reduced, corresponding to plate 3'' (Fig. 3E). The operculum was monoplacate and free (Fig. 3B).
377 Claustra (large arched openings) could be observed at the base of the parasutures (Fig. 3C).

378 Cells of *Gonyaulax amoyensis* strain TIO711 were 23.8–42.4 μm long (mean = $32.6 \pm 3.7 \mu\text{m}$,
379 n=28) and 19.2–29.1 μm wide (mean = $25.2 \pm 2.8 \mu\text{m}$, n=28). Cells had a conical epitheca with
380 intermediate shoulders and a rounded hypotheca (Fig. S4, A and B). There were numerous bean-
381 shaped chloroplasts located in the periphery of the cell (Fig. S4, A and B). The nucleus was
382 elongated and located in the hypocone (Fig. S4, C and D).

383 Thecae had a sexiform gonyaulacoid tabulation in the hypotheca with an S-type ventral
384 organization and neutral torsion (Fig. 4, A and C). The pore plate was lanceolate in shape and
385 surrounded by raised ridges of neighboring apical plates (Fig. 4A). Plates 1' and 4' were very
386 narrow (Fig. 4, D and F). The cingulum was situated in the equatorial part of the cell, descending
387 with a displacement of 2-3 cingulum widths (Fig. 4, A and B). The cingulum overhang was 1.8 to
388 2.5 widths (Fig. 4G).

389 Plate 1'''' had numerous short spines ca. 0.6 μm long (Fig. 4H). The sulcus was wide in the

390 anterior and posterior part but narrow in the central part. It was comprised of plates Sa, Ssa, Ssp,
391 Sda, Sdp and Sp (Fig. 4, A and I). A schematic plate pattern is provided in Figure S5. Plates 3''
392 and *4''' were identified as the keystone plates (Fig. 4C).

393

394 ***Gonyaulax portimonensis* sp. nov. K.N.Mertens, A.Amorim**

395 **& H.Gu sp. nov. (Figs. 5, 6, Fig. S6 in the Supporting Information)**

396 *Description.* Cells were 30–43 µm long and 24–39 µm wide with 2–4 short antapical spines,
397 often with a pronounced right antapical horn. Epitheca was conical with short shoulders. Cell
398 surface was thick and formed dense reticulations. Cingulum was located in the equatorial part of
399 the cell and descended with a displacement and overhang of about 2.0 times its width. Cells
400 displayed a plate formula of Po, Cp, 4', 6'', 6C, 6S, 5''', 1p, 1'''' . Angle between the major axis and
401 line joining ends of cingulum was approximately 25–40°. Cyst was subspherical to ellipsoidal, 42–
402 48 µm long and 32–38 µm wide with apical boss. Cyst had gonial, petaloid processes, 12–14 µm in
403 length, connected by low sutural crests. Cyst wall was formed of a smooth pedium and a tegillum
404 that form small blisters and hollow undulations over the surface. Paracingulum descended with
405 displacement of three times its width. Archeopyle was not reduced and corresponded to plate 3''.

406 *Holotype* (designated here): FR CEDiT2022H136, SEM stub containing the type specimen from a
407 culture established from a cyst isolated from surface sediment collected on October 8, 2019, by
408 Véronique Séchet and K.N.Mertens. Dinoflagellate type collection in the Centre of Excellence for
409 Dinophyte Taxonomy (CEDiT, Wilhelmshaven, Germany).

410 *Type locality.* Portimão Port, Portugal (37°7.20' N, -8°31.59' E).

411 *Habitat.* Marine and planktonic with benthic cyst stage.

412 *Etymology.* The epithet '*portimonensis*' is derived from Portimão, and refers to the type locality.

413 *GenBank accession numbers.* OM177644 (SSU), OM228730 (LSU).

414 *Remarks.* The cyst resembles the fossil-based taxon *Spiniferites ristingensis* (see discussion).

415 *Morphology.* Cysts of *Gonyaulax portimonensis* were ovoid, 41.7–47.7 μm (mean = 45.0 \pm 3.0
416 μm , n=3) long and 31.9–38.3 μm (mean = 36.0 \pm 3.6 μm , n=3) wide (Fig. 5A). They were
417 ornamented with processes 11.5–14.0 μm in length (mean = 12.9 \pm 1.0, n=9), and connected by
418 low sutural crests, but sometimes by high membranous flanges (Fig. 5B). The cingulum
419 descended with three times of its width (Fig. 5C). The cyst wall, ca 1.3 μm thick, was formed of a
420 smooth pedium and a tegillum that formed small blisters and hollow undulations over the surface,
421 that appeared granulate (Fig. 5B). The processes were gonal, petaloid, forming polygonal
422 platforms (Fig. 5C). A low apical boss was observed (Fig. 5A). Parasulcal plates were expressed.
423 The archeopyle was not reduced, corresponding to plate 3'' (Fig. 5D). The operculum was
424 monoplacate and free.

425 Cells of *Gonyaulax portimonensis* strain IFR20-019 were 30.0–42.9 μm long (mean = 34.8 \pm
426 3.7 μm , n= 17) and 24.4–38.6 μm wide (mean = 30.6 \pm 3.6 μm , n= 17). Cells had a conical
427 epitheca with intermediate shoulders and a rounded hypotheca (Fig. S6A). There were numerous
428 bean-shaped chloroplasts located in the periphery of the cell (Fig. S6, B and C). The nucleus was
429 large and located in the hypocone (Fig. S6C).

430 The thecae had a sexiform gonyaulacoid tabulation (Fig. 6E) with an S-type ventral
431 organization and neutral torsion (Fig. 6, A and B). The pore plate was lanceolate in shape and
432 surrounded by raised ridges of neighboring apical plates (Fig. 6, C and D). There was a ventral
433 pore between plates 4'a and 4'p (Figs. 6D, S6D). The cingulum descended with a displacement of
434 two cingulum widths (Figs. 6A, S6A). The cingulum overhang was ca. two widths. Plate 1'''' had
435 2–4 short spines 1.5–4.3 μm long (Fig. 6, B and E). The sulcus was narrow in the middle but wide
436 in the anterior and posterior parts. It was comprised of plates Sa, Ssa, Ssp, Sda, Sdp and Sp (Fig.
437 6F). A schematic plate pattern is provided in Figure S7 in the Supporting Information. Plates 3''
438 and *4''' were identified as the keystone plates (Fig. 6, B and E).

439
440 *Gonyaulax baltica*

441 *Morphology.* Cells of Korean strain LIMS-PS-3408 were 27.6–44.5 μm long (mean = 35.1 \pm 4.2
442 μm , n= 30) and 23.0–34.9 μm wide (mean = 28.7 \pm 2.6 μm , n= 30). Cells had a conical epitheca

443 with intermediate shoulders and a rounded hypotheca (Fig. S8A in the Supporting Information).
444 There were numerous bean-shaped chloroplasts located in the periphery of the cell (Fig. S8B). The
445 nucleus was variable ranging from L-shaped to short curved, located in the hypocone (Fig. S8, D–
446 F).

447 Cells had a plate formula of Po, Cp, 4', 6'', 6C, 6S, 5''', 1p, 1'''' (Fig. 7). The thecae had a
448 sexiform gonyaulacoid hypotheca tabulation with a S-type ventral organization and neutral torsion
449 (Fig. 7, A and B). The pore plate was lanceolate in shape and surrounded by raised ridges of
450 neighboring apical plates (Fig. 7C). There was a ventral pore between plates 4'a and 4'p (Fig. 7C).
451 The cingulum descended with a displacement of three cingulum widths (Fig. 7A). The cingulum
452 overhang was ca. 2.5 widths. The angle between the major axis and a line joining the ends of the
453 cingulum was approximately 40–45°. Plate 1'''' had numerous short spines ca. 0.6 µm long (Fig. 7,
454 A and E). The sulcus was narrow in the middle but widened towards anterior and posterior parts. It
455 comprised of plates Sa, Ssa, Ssp, Sda, Sdp and Sp (Fig. 7F).

456 *Gonyaulax baltica* formed a dense, visible bloom (4.8×10^6 cells · L⁻¹) in Māori Bay, New
457 Zealand in May, 2019. Cells from the bloom sample were 30.0–35.7 µm long (mean = 33.6 ± 1.6
458 µm, n= 18) and 28.8–35.0 µm wide (mean = 32.1 ± 1.8 µm, n= 18). The cell morphology was
459 similar to those from South Korea, but differed in having several antapical spines as long as 6.0
460 µm (Fig. 8, A–F).

461 Living cysts from surface sediment of Māori Bay displayed an oval central body, and were 33.3
462 µm long and 30.7 µm wide, with a small apical boss (Fig. 8G). The paracingulum descended with
463 a displacement of twice its width (Fig. 8H).

464 The cyst had a wall ca. 2 µm thick ornamented with exclusively gonial, trifurcate processes 11.1–
465 14.2 µm long (Fig. 8, G and H). There was one hypothecal petaloid trumpet-shaped process (Fig.
466 8I).

467 *Molecular phylogeny.*

469 *Gonyaulax bohaiensis* strains (TIO724, 725, 726, 727, 731, LIMS-PS-3448) shared identical LSU
470 rRNA gene sequences and differed from *G. baltica* (= *Impagidinium caspiense*, GenBank

471 LC222302) at 42 positions (96.60% similarity), from French (GenBank MW775689) and Japanese
472 (GenBank LC222310) *Spiniferites belerius* sequences at 72 and 86 positions (89.71% and 93.06%
473 similarity), from *G. portimonensis* (GenBank OM228729) at 78 positions (87.74% similarity), and
474 from *I. pallidum* (GenBank LC222304) at 297 positions (75.81% similarity). *Gonyaulax*
475 *amoyensis* strains (TIO708, 709, 710, 711, 719, 722) differed from each other only at one position.
476 They differed from *G. bohaisensis* strain TIO724 at 41 positions (96.99% similarity) and from *G.*
477 *baltica* strain LIMS-PS-3408 at 92 positions (91.50% similarity). *Gonyaulax baltica* strain LIMS-
478 PS-3408 from Korea shared identical sequences with strain CAWD374 from New Zealand and
479 differed from French and Japanese *Spiniferites belerius* sequences cited above at 83 positions and
480 1 position respectively (88.09% and 99.91% similarity).

481 ML and BI analyses based on LSU rRNA gene sequences yielded similar phylogenetic trees.
482 The ML tree displayed five well-resolved clades (Fig. 9) corresponded to the families Ceratiaceae,
483 Protoceratiaceae, Pyrophacaceae, Gonyaulacaceae and Lingulodiniaceae. Gonyaulacaceae was
484 monophyletic comprising the extant genus *Gonyaulax* and several fossil-based genera
485 (*Ataxiodinium*, *Bitectatodinium*, *Impagidinium*, *Spiniferites*, and *Tectatodinium*) with maximal
486 support (ML BS:100; BI PP: 1.0). There were two well resolved clades (I and II) receiving strong
487 support (100; 0.99) or maximal support. Clade I comprised *G. spinifera*, *G. polygramma*, *G.*
488 *hyalina*, *G. ellegaardiae*, *G. elongata*, *G. membranacea* and related species. Clade II comprised *G.*
489 *bohaisensis*, *G. amoyensis*, *G. portimonensis*, and *G. baltica*. *Impagidinium pallidum* was sister to
490 Clade II on a long branch. *Gonyaulax baltica* comprised two ribotypes with maximal support.
491 Ribotype A included strains from the Atlantic, whereas ribotype B included strains from the
492 Pacific.

493 For SSU rRNA gene sequences comparison, *Gonyaulax amoyensis* strain TIO708 differed from
494 *Impagidinium caspiense* (GenBank LC222300) at 40 positions (97.68% similarity), from
495 *Spiniferites belerius* (GenBank LC222309) at 69 positions (96.00% similarity), from *G.*
496 *portimonensis* (OM177644) at 58 positions (96.59% similarity), from *G. baltica* strains (GenBank
497 OM177651, OM1776512, OM1776513) at 56 positions (96.40% similarity). *Gonyaulax*
498 *bohaisensis* strains TIO726 and TIO729 shared identical SSU sequences and differed from *G.*

499 *amoyensis* (GenBank OM177648) at 42 positions (97.44% similarity). ML and BI analysis based
500 on SSU rRNA sequences yielded the same results as LSU rRNA sequences (Fig. 10).

501

502 *Yessotoxins*.

503 Six strains of *Gonyaulax amoyensis*, *G. baltica*, *G. bohaiensis*, and *G. portimonensis* were studied
504 for YTXs. Very low concentrations of YTX were detected in the *G. bohaiensis* strain TIO732
505 (0.17 ± 0.02 fg/cell). None of the 21 other analogues were detected. YTX was not detected in the
506 other five strains, but the limits of detection were greater than this low cell quota (Table 1) due to
507 the limits of available biomass. Cell concentrates from bloom samples in Māori Bay and cultured
508 cells were analysed for YTX by LC-MS/MS. The screened analogs were YTX, homo-YTX, 45Oh-
509 YTX and 45OH-homoYTX. No trace of any of these analogues was detected.

510

511 **DISCUSSION**

512 *Cyst-theca relationship of Impagidinium variaseptum, Spiniferites pseudodelicatus and S.*
513 *ristingensis*.

514 Previously eleven *Spiniferites* and one *Impagidinium* species have been linked to specific
515 *Gonyaulax* species. Here we clarify the cyst-theca relationships of *I. variaseptum* and *S.*
516 *ristingensis* for the first time (Table S1). A new *Spiniferites* species, *S. pseudodelicatus* is
517 described, and its corresponding motile cells are revealed. *Gonyaulax baltica* ribotype B is linked
518 to *Spiniferites belerius*.

519 *Impagidinium variaseptum* from the Bohai Sea accords with the original description by the
520 presence of septa of variable height and an apical boss (Marret and de Vernal 1997). Bohai Sea
521 cysts are relatively smaller (36.0–40.5 μm long vs. 47.0–75.0 μm long) with a well expressed
522 paratabulation, a microgranulate wall and parasutural septa 2.0–7.6 μm high. According to Marret
523 and de Vernal (1997), *I. variaseptum* lacks paratabulation in the sulcal area, but their plate III, fig.
524 5 shows a specimen that at least suggests a posterior sulcal plate. Cysts of *Impagidinium* from the

525 Bohai Sea are morphologically similar to *I. caspiense*, but the latter has lower sutural septa
526 (1.3–4.3 vs 2.0–7.6 μm ; Mertens et al. 2018a). Cysts of *Impagidinium* from the Bohai Sea are also
527 morphologically similar to *I. japonicum*, but the latter lacks an apical boss and has well developed
528 septa as high as one third of the cyst diameter (Matsuoka 1983).

529 *Impagidinium variaseptum* has been reported only from recent sediments, from the Indian
530 Ocean (Marret and de Vernal 1997), from west of Tasmania and the southwestern Pacific Ocean,
531 and from east of New Zealand (Sun and McMinn 1994). Our findings of *I. variaseptum* in the
532 coastal waters of Bohai Sea support its occurrence in a neritic environment, in contrast to the
533 oceanic habitat of all other *Impagidinium* species (Marret and de Vernal 1997), except for *I.*
534 *caspiense* restricted to the Caspian and Aral Seas (Zonneveld et al. 2013) also neritic habitats.

535 *Spiniferites ristingensis* from Portugal matches the original description of *S. ristingensis*,
536 sharing a low apical boss, low sutural crests connecting the processes, numerous blisters and
537 hollow undulations on the cyst surface, exclusively gonal processes with petaloid tips, and a girdle
538 displaced with three times its widths (Head 2007). *Spiniferites ristingensis* was previously
539 reported in the Baltic Sea of the Eemian age (ca. 127,000 years ago) when water temperatures
540 were considered to be at least 5°C higher than at present (Head 2007). The species was reported
541 from recent sediments of Brittany, France (Gurdebeke et al. 2018), the Black Sea and off
542 Southwestern Portugal (Mertens et al. 2018b), from surface sediments from the West coast of
543 Portugal (as *S. delicatus*, Ribeiro and Amorim 2008; and as *S. delicatus/ristingensis*, Ribeiro et al.
544 2016). It was also reported further north along the Spanish coast (the Ría de Vigo, NW Iberia), as
545 *Spiniferites* Vigo-type cf. *S. ristringensis* (Head 2007, García-Moreiras et al. 2018).

546 *Spiniferites pseudodelicatus* from the East China Sea is superficially similar to *S. delicatus*,
547 sharing a low apical boss, high sutural flanges connecting the processes, processes with petaloid
548 tips, and a girdle displaced three times its widths (Reid 1974). However, South China Sea cysts of
549 *S. pseudodelicatus* bear undeveloped intergonal process and are somewhat smaller (28.7–39.6 μm
550 long) than the topotype material (40.0–60.0 μm long, Reid 1974; 36.8–50.8 μm long, Gurdebeke
551 et al. 2018). In addition, these two species differ in wall ornamentation (Table 2). Therefore, we
552 described a new species, *Spiniferites pseudodelicatus*. Our finding of *S. pseudodelicatus* in

553 Xiamen Bay suggests that it prefers a neritic environment.

554

555 *Discrimination of non-fossil species.*

556 Motile cells of *Gonyaulax bohaiensis*, *G. amoyensis* and *G. portimonensis* are morphologically
557 similar. All of them share a large cingulum displacement and overhang and numerous minute
558 antapical spines. Several prominent antapical spines were reported in the *Gonyaulax spinifera*
559 complex, such as *G. spinifera*, *G. digitale* (Kofoid 1911), *G. ellegaardiae* (Mertens et al. 2015), *G.*
560 *membranacea*, and *G. elongata* (Ellegaard et al. 2003), but such spines are not observed in motile
561 cells of *G. bohaiensis*, *G. amoyensis* and *G. portimonensis*. In the size of antapical spines, they are
562 much closer to *G. scrippsae*, but can be differentiated by the cingulum overhang, the number of
563 antapical spines and surface reticulation (Table 3).

564 Motile cells of *Gonyaulax bohaiensis* and *G. amoyensis* are similar to *G. baltica*. All of them
565 share a ventral pore between 4'a and 4'p, and only minor differences could be identified that do not
566 enable unambiguous morphological identification based on the motile stage (Table 3). The ridge
567 around apical pore complex is high in *G. bohaiensis*, but low in *G. amoyensis* and *G. baltica*.
568 *Gonyaulax portimonensis* has a relatively larger antapical spine in the right side but in other three
569 species the antapical spines are equal in length. *Gonyaulax portimonensis* resembles *G.*
570 *monacantha* (Pavillard 1916), but is smaller (30.0–42.9 vs 45–55 µm long). *Gonyaulax*
571 *portimonensis* also resembles *G. cochlea* (Meunier 1919) but has a larger cingulum displacement
572 (2.0 cingulum width vs 1.0). Based on morphological characteristics from both motile stages and
573 cysts, we proposed *G. bohaiensis* as the motile stage of *I. variaseptum*, and *G. amoyensis* and *G.*
574 *portimonensis* corresponding to cysts resembling *S. pseudodelicatus* and *S. ristingensis*
575 respectively. On the other hand, *G. baltica* is able to produce cysts resembling *I. caspiense* and
576 *S. belerius* (Mertens et al. 2018a, present study).

577 The *Gonyaulax baltica* strain LIMS-PS-3408 from Korea and a bloom sample of *Gonyaulax*
578 *baltica* from New Zealand are indistinguishable from the type material in morphology, but
579 genetically separated from *G. baltica* of the Baltic Sea. The number and length of antapical spines
580 appear slightly plastic in *G. baltica* ribotype A, e.g., strains from the Caspian Sea show numerous

581 minute spines ca 1.0 μm long (Mertens et al. 2018a), but can be 2.0 μm long in cells from the
582 Baltic Sea (Ellegaard et al. 2002). Similar variation was also observed in *G. baltica* ribotype B;
583 strains from South Korea show numerous minute spines but the bloom sample from New Zealand
584 show longer and fewer spines.

585

586 *Molecular phylogenetics.*

587 Our molecular phylogenies, based on LSU and SSU rRNA gene sequences, are congruent and
588 both of them support monophyly of the extant genus *Gonyaulax*, but indicates two clades within
589 the genus. Clade I includes *G. spinifera* like species with two prominent antapical spines, such as
590 *G. digitale*, *G. membranacea*, *G. elongata*, *G. ellegaardiae*, *G. nezaniae* as well as those without
591 spines, such as *G. hyalina*. In contrast, Clade II includes *G. baltica* like species with relatively
592 short and numerous antapical spines, as also observed in *G. bohaiensis*, *G. amoyensis*, and *G.*
593 *portimonensis*. Kofoid (1911) proposed the subgenus *Gonyaulax* that was defined to include
594 species with spheroidal or polyhedral cells, Therefore, species of both Clades I and II can be
595 classified within this subgenus, but the subgenus appears polyphyletic. DNA sequences of
596 subgenera *Acanthogonyaulax* and *Fusigonyaulax*, characterized by an elongated apical and one or
597 two antapical horns (Kofoid 1911), are not available. The subgenus *Steiniella* includes *G. fragilis*
598 and *G. hyalina* (Carbonell-Moore and Mertens 2019), however, *G. hyalina* is also nested within
599 Clade I. One subgenus for Clade I and another for Clade II could be recognized based on the
600 number, size of antapical spines in motile cells or the shape of processes in cysts.

601 The neritic *Impagidinium caspiense* and *I. variaseptum* (as *Gonyaulax bohaiensis*) are in the
602 same clade (Clade II) while oceanic *I. pallidum* is sister to Clades II on a long branch (Figs. 9, 10).
603 Currently DNA sequences of extant oceanic *I. japonicum*, *I. paradoxum*, *I. patulum* and *I.*
604 *aculeatum*, *I. plicatum*, *I. sphaericum* and *Impagidinium velorum* are not available. It will be
605 interesting to see if the morphological criteria like the shape of plate 6", height of septa and
606 presence/absence of an apical boss might support the split of *Impagidinium* into one genus for
607 neritic species and another for oceanic species.

608 The grouping of *Spiniferites pseudodelicatus*, *S. ristingensis* and *S. belerius* in the same clade

609 with *Impagidinium* instead of with other *Spiniferites* species challenges the current taxonomic
610 criteria based on morpho-anatomy. *Spiniferites pseudodelicatus* and *S. ristingensis* share high
611 flanges that connect the processes as also observed in *I. variaseptum* and *I. caspiense*
612 (Gurdebeke et al. 2018, Mertens et al. 2018a). Reduced process length in cysts of *Gonyaulax*
613 *baltica*/*I. caspiense* was attributed to low salinity as demonstrated in culture experiments and a
614 field survey (Dale 1996, Ellegaard et al. 2002). However, the short processes in *I. variaseptum*
615 appear not to be related with low salinity as they were found in seawater with typical salinity
616 values. *Spiniferites membranaceus* and *S. mirabilis* also have a high flange, but it is only present
617 in the antapical plate. The fact that *S. mirabilis* is sister to *S. membranaceus* in the SSU based
618 phylogeny (Fig. 10) suggests that this character might be taxonomically significant as well.

619 Petaloid processes appear to be characteristic of cysts produced by *Gonyaulax baltica* and
620 related species, as observed in *Spiniferites pseudodelicatus*, *S. ristingensis*, *S. belerius* (Mertens et
621 al. 2018a) and in cysts produced in cultures of *G. baltica* (Ellegaard et al. 2002), suggesting that
622 this trait is phylogenetically significant. *Spiniferites delicatus* also has petaloid processes (Reid
623 1974), and needs to be sequenced to see if it is in the same clade as *G. baltica*.

624 Our findings reveal two ribotypes of *Gonyaulax baltica* as well as the first record of a bloom by
625 this species. Ribotype B of *G. baltica* from the Pacific cannot be differentiated morphologically
626 from ribotype A in the Atlantic, suggesting that this is a cryptic species. Whether ribotype B is
627 able to generate *Impagidinium* like cysts in low salinity as ribotype A does remain to be
628 determined. The low genetic similarity between the two ribotypes of *G. baltica* (around 88%) is
629 comparable to *Sourniaea diacantha* (86%), which also shows two ribotypes of Atlantic and Pacific
630 origin (Zhang et al. 2020).

631
632 *Yessotoxin production.*

633 The finding of a very low YTX cell quota of *Gonyaulax bohaisensis* strain TIO732 is noteworthy,
634 even though no YTX was detected in the other two strains (TIO726 and TIO711). The detection
635 limits of these two measurements (1.34 and 0.4 fg · cell⁻¹, respectively) were above the YTX cell
636 quota of strain TIO732 (0.17 fg · cell⁻¹) due to lower biomass and the use of a different instrument.

637 For this reason, the lack of YTX detection in strains TIO726 and TIO711 does not necessarily
638 indicate its absence. YTX production has been well documented in the *G. spinifera* group (*G.*
639 *membranacea* and *G. ellegaardiae*; Chikwililwa et al. 2019, Pitcher et al. 2019), but our results
640 suggest that YTX production may also occur in the *G. baltica* clade, even though there are not
641 many records.

642

643 *Dinoflagellate Nomenclature.*

644 The International Code of Nomenclature for algae, fungi and plants (ICN, Turland et al. 2018)
645 sanctions the use of dual nomenclature: it allows fossil- and non-fossil taxa to have separate names
646 even if they are linked. This dual nomenclature system has been applied to dinoflagellates for
647 decades. Attribution of living dinoflagellate cysts to motile stages have been investigated
648 intensively (Wall 1967, Wall and Dale 1968, Ellegaard et al. 2003, Mertens et al. 2015, Gu et al.
649 2021). However, there remain many unresolved issues, especially for those living “fossil” cysts
650 such as *Spiniferites*. Here we relate several new *Gonyaulax* species with resting stages resembling
651 *Impagidinium variaseptum*, *Spiniferites pseudodelicatus* and *S. ristingensis*, respectively. Future
652 work should contribute to the unification of nomenclature, but clearly there is still much work to
653 be done before this can be achieved. Therefore, in the present work we chose to use the dual
654 nomenclature.

655

844 Fig. 1. Micrographs of cysts of *Gonyaulax bohaisensis* from the Bohai Sea, China, resembling
845 *Impagidinium variaseptum*. Tabulation labeling follows Kofoid (1911) and Balech (1980). (A)
846 Bright-field light microscopy. (B–F) Scanning electron microscopy. (A) A living cyst showing the
847 yellow accumulation body and sutural septa of variable height. (B) Ventral view of a living cyst
848 showing a ventral pore (arrow). (C) Apical view of a living cyst showing two apical (2', 3') and
849 five precingular plates (1''–5''). (D) Dorsal view of an empty cyst showing the reduced archeopyle
850 (arrow). (E) Antapical view showing five postcingular (*2'''–*6''') plates, one antapical plate (1''''')
851 and one intercalary plate (1p) (F) Ventral view of a living cyst showing the anterior sulcal plate
852 (Sa), anterior left sulcal (Ssa) plate, posterior left sulcal (Ssp), right anterior sulcal plate (Sda),
853 right posterior sulcal plate (Sdp), and posterior sulcal plates (Sp). Scale bars = 10 μm .

854
855
856 Fig. 2. Scanning electron micrographs of *Gonyaulax bohaisensis* strain TIO726 from the Bohai
857 Sea, China. (A) Ventral view showing cingulum displacement and overhang. (B) Dorsal
858 view showing four precingular (2''–5''), and two postcingular (*4''', *5''') plates. (C) Apical
859 view showing six precingular (1''–6''), and two apical (2', 3') plates. (D) Apical-ventral view
860 showing the first and fourth apical plates (1', 4') and a ventral pore (arrow). (E) The
861 cingulum showing six cingular plates. (F) Antapical view showing five postcingular (*2''''–
862 *6''') plates, one antapical plate (1''''') and one intercalary plate (1p). (G) Sulcal plates
863 showing the anterior left sulcal plate (Ssa), anterior right sulcal plate (Sda), posterior left
864 sulcal plate (Ssp), posterior right sulcal plate (Sdp) and posterior sulcal plate (Sp). Scale bars
865 = 4 μm , except in (A–C) = 10 μm .

866
867
868 Fig. 3. Micrographs of *Gonyaulax amoyensis* cysts from Xiamen Bay, China (A, B, D) and
869 *Spiniferites pseudodelicatus* from the South China Sea (C, E, F). (A, B) Bright-field light
870 microscopy. (C–F) Scanning electron microscopy. (A) An empty cyst showing the
871 undeveloped intergonal process (arrow) and membrane connecting gonol processes

872 (arrowhead). (B) Dorsal view of an empty cyst showing the reduced archeopyle (arrows).
873 (C) Ventral view of an empty cyst showing the cingulum displacement, claustra (arrowhead)
874 and petaloid processes (arrow). (D) Apical view of a living cyst showing the apical plates. (E)
875 Dorsal view of a living cyst. (F) Antapical view of a living cyst. Scale bars = 10 μ m.

877 Fig. 4. Scanning electron micrographs of *Gonyaulax amoyensis* strain TIO711 from Xiamen Bay,
878 China. (A, B) Ventral view showing cingulum displacement and overhang. (C) Dorsal view
879 showing three precingular (2''–4''), and two postcingular (*3''', *4''') plates. (D) Lateral view
880 showing three precingular (4''–6''), three apical plates (1', 3', 4') plates. (E) Apical view
881 showing three precingular (1''–3''), and two apical (2', 3') plates. (F) Ventral view showing
882 the two apical (1', 4') plates and a ventral pore (arrow). (G) The cingulum showing six
883 cingular plates. (H) Antapical view showing five postcingular (*2''''–*6''') plates, one
884 antapical plate (1''''') and one intercalary plate (1p). (I) Sulcal plates showing the anterior left
885 sulcal plate (Ssa), anterior right sulcal plate (Sda), posterior left sulcal plate (Ssp), posterior
886 right sulcal plate (Sdp) and posterior sulcal plate (Sp). Scale bars = 10 μ m.

887
888 Fig. 5. Light micrographs of cysts resembling *Spiniferites ristingensis* from Portugal. (A) An
889 empty cyst showing the ovoid body and a low apical boss. (B) Apical-ventral view of an
890 empty cyst showing the apical plates. (C) Ventral view of an empty cyst showing the
891 cingulum displacement (arrows). (D) Dorsal view of an empty cyst showing the archeopyle
892 not reduced (arrows). Scale bars = 10 μ m.

893
894 Fig. 6. Scanning electron micrographs of *Gonyaulax portimonensis* from Portugal. (A) Ventral
895 view showing cingulum displacement and overhang and a pronounced antapical spine. (B)
896 Dorsal view showing three precingular (3''–5''), and two postcingular (*4''', *5''') plates. (C)
897 Apical view showing six precingular (1''–6''), and two apical (2', 3') plates. (D) Apical view
898 showing the four apical (1'–4') plates, APC and a ventral pore (arrow). (E) Antapical view
899 showing five postcingular (*2''''–*6''') plates, one antapical plate (1''''') and one intercalary

900 plate (1p). (F) Sulcal plates showing the anterior left sulcal plate (Ssa), anterior right sulcal
901 plate (Sda), posterior left sulcal plate (Ssp), posterior right sulcal plate (Sdp) and posterior
902 sulcal plate (Sp). Scale bars = 5 μm , except in (D) = 2 μm .

903

904 Fig. 7. Scanning electron micrographs of *Gonyaulax baltica* strain LIMS-PS-3408 from South
905 Korea. (A) Ventral view showing cingulum displacement and overhang. (B) Dorsal view
906 showing three precingular (2''–4''), and two postcingular (*4''', *5''') plates. (C) Apical view
907 showing two apical (1', 4') plates, and a ventral pore (arrow). (D) Apical view showing six
908 precingular (1''–6''), and two apical (2', 3') plates. (E) Antapical view showing five
909 postcingular (*2'''–*6''') plates, one antapical plate (1''''') and one intercalary plate (1p). (F)
910 Sulcal plates showing the anterior left sulcal plate (Ssa), anterior right sulcal plate (Sda),
911 posterior left sulcal plate (Ssp), and posterior sulcal plate (Sp). Scale bars = 10 μm .

912

913 Fig. 8. Micrographs of *Gonyaulax baltica* from New Zealand. (A–F) Scanning electron
914 microscopy. (G–I) Bright-field light microscopy. (A) Ventral view showing cingulum
915 displacement and overhang. (B) Apical view showing six precingular (1''–6''), and two
916 apical (2', 3') plates. (C) Apical view showing two apical (1', 4') plates, and a ventral pore
917 (arrow). (D) Dorsal view showing three precingular (2''–4''), and two postcingular (*4''',
918 *5''') plates. (E) Internal view showing six cingular plates. (F) Antapical view showing five
919 postcingular (*2'''–*6''') plates, one antapical plate (1''''') and one intercalary plate (1p). (G)
920 Mid-focus of a living cyst showing two prominent antapical processes. (H) High focus of a
921 living cyst showing the paracinglum. (I) High focus of a living cyst showing the trumpet
922 shaped process (arrow). Scale bars = 10 μm , except in (C) = 5 μm .

923

924 Fig. 9. Phylogeny including *Gonyaulax bohaisensis*, *G. portimonensis* and *G. amoyensis* inferred
925 from partial LSU rRNA (D1–D6) gene sequences using maximum likelihood (ML). New
926 sequences are indicated in bold and red. Five families are labeled and marked with vertical
927 solid lines on the right. Two clades (I and II) of Gonyaulacaceae are labeled and marked

928 with vertical dashed line on the right. Branch lengths are drawn to scale, with the scale bar
929 indicating the number of nucleotide substitutions per site. Numbers on branches are
930 statistical support values for clusters to the right (left: ML bootstrap support values; right:
931 Bayesian posterior probabilities).

932
933 Fig. 10. Phylogeny including *Gonyaulax bohaiensis*, *G. portimonensis* and *G. amoyensis* inferred
934 from partial SSU rRNA gene sequences using maximum likelihood (ML). New sequences
935 are indicated in bold and red. Five families are labeled and marked with vertical solid lines
936 on the right. Two clades (I and II) of Gonyaulacaceae are labeled and marked with vertical
937 dashed line on the right. Branch lengths are drawn to scale, with the scale bar indicating the
938 number of nucleotide substitutions per site. Numbers on branches are statistical support
939 values for clusters to the right (left: ML bootstrap support values; right: Bayesian posterior
940 probabilities).
