Abstract :

Dual nomenclature in dinoflagellates is supported under the current nomenclatural code for algae, fungi and plants and allows a fossil-defined (usually cyst) species to bear a name other than that of its equivalent non-fossil species, as established for example by incubation experiments. Two names can then apply to the same cyst morphotype, reflecting the separate concepts and criteria used for fossil- and non-fossil taxa. Fossil-species are normally and logically assigned to fossil-genera and non-fossil species to non-fossil genera, a practice that facilitates dual nomenclature. Inconsistencies and ambiguities arise when binomials combine the names of fossil- with non-fossil taxa. Examples of this hybridized nomenclature and its consequences are examined, with problems identified and potential solutions discussed. Accordingly, a new non-fossil genus *Lingulaulax* is proposed with *Lingulaulax polyedra* (von Stein 1883) comb. nov. as its type and equivalent to the fossil-species *Lingulodinium machaerophorum* (Deflandre and Cookson 1955) Wall 1967, along with the new combination *Lingulaulax milneri* (Murray and Whitting 1899); the genus *Lingulodinium* Wall 1967 is retained in its exclusively fossil status. The non-fossil name *Gonyaulax ellegaardiae* Mertens et al. 2015 is validly published herein

Keywords : Dinocyst, taxonomy, dual nomenclature, hybridized names, *Lingulodinium*, *Lingulaulax*

42 41 **1. Introduction**

43
44
45 42

46
47 43 Separate taxonomic and nomenclatural traditions have arisen independently among

48
49 44 paleontologists studying fossils and biologists examining the entire life cycle. A fossil-

50
51 45 species has a holotype that is a fossil, and a non-fossil species has a holotype that is not a

52
53
54 46 fossil (Gravendyck et al. 2021). When a named fossil-species is linked, usually by

1
2
3 47 germination studies, to a named species defined using non-fossil (living) material, then
4
5 48 two names are available for the same cyst morphotype; no formal rules determine which
6
7
8 49 of these name is used. This is dual nomenclature. The International Code of
9
10 50 Nomenclature for algae, fungi and plants (ICN, Turland et al. 2018), which governs the
11
12 51 naming of dinoflagellate taxa, allows fossil- and non-fossil taxa to have separate names
13
14
15 52 even when they are subsequently demonstrated to be linked (see Section 3 below). The
16
17 53 ICN therefore sanctions the use of dual nomenclature.

18
19 54 The confirmed fossil record of dinoflagellates (division Dinophyta) extends back
20
21 55 to the Middle or Late Triassic (e.g. Mangerud et al. 2019) and has been studied
22
23
24 56 extensively (e.g. Stover et al. 1996). This record is based almost exclusively on the cyst
25
26 57 stage of the life cycle, as the motile stage rarely preserves (Head 1996). For most species
27
28 58 with a fossil record, the cysts are organic-walled and appear in palynological
29
30
31 59 preparations. This article primarily addresses formally named dinoflagellate taxa that
32
33 60 produce organic-walled cysts, although many aspects will be relevant also to
34
35 61 dinoflagellate cysts with calcareous walls.

36
37
38 62 Downie et al. (1961) proposed that all dinoflagellates should be treated under the
39
40 63 botanical code (now the ICN) rather than the International Code of Zoological
41
42 64 Nomenclature (ICZN, Ride et al. 2020) to promote stability and consistency, but also
43
44
45 65 because the botanical code, unlike the ICZN, provides for the use distinct fossil taxa (the
46
47 66 successor to “form-genera” as referenced by Downie et al. 1961; see Subsection 3.1
48
49 67 below) which allows the use of dual nomenclature. Presently, all fossil dinoflagellate cyst
50
51 68 researchers and nearly all biologists treat dinoflagellates under this code. Nonetheless,
52
53
54 69 because dinoflagellates as a group include heterotrophs, mixotrophs, symbionts and
55
56
57
58
59
60

1
2
3 70 parasites as well as phototrophs (e.g. Schnepf and Elbrächter, 1992), some biologists (e.g.
4
5 71 Balech 1944 et seq., see Head 1996, p. 1227; Coats et al. 2012, p. 4; Choi et al. 2021)
6
7
8 72 have treated dinoflagellates as protozoans and hence named them under the ICZN. Names
9
10 73 “available” (validly published) under the ICZN are automatically accepted as validly
11
12 74 published when treated under the ICN (Art. 45), where dual nomenclature then applies.
13
14
15 75 The ICZN recognizes only those names treated as “as animals for the purpose of
16
17 76 nomenclature” (ICZN Art. 1.1.1). Notably, the ICN requires that the code used by the
18
19 77 author be “determined through internal evidence, irrespective of any claim by the author
20
21 78 as to the group of organisms to which the taxon is assigned” (Art. 45.1). Evidence of
22
23 79 using the ICZN would include the suffixes chosen for suprageneric names (e.g. “-ida” or
24
25 80 “-idae” for familial names in the ICZN, rather than “-aceae” under the ICN) and the
26
27 81 application of stem augmentation for specific and subspecific epithets (e.g. the specific
28
29 82 epithet *tregouboffi*, rather than *tregouboffii* under the ICN). We propose in the interests of
30
31 83 nomenclatural stability (see Head, 1996, p. 1227 for further discussion) that such internal
32
33 84 evidence extend to the *absence* of a Latin diagnosis as this has never been required under
34
35 85 the ICZN. For example, on this basis we accept that Halim (1960) described the
36
37 86 important non-fossil genus *Alexandrium* and its holotype species *Alexandrium minutum*
38
39 87 under the ICZN, contrary to the views of Woelkerling and Moestrup (2022, but see also
40
41 88 McNeill 2023), and is therefore validly published under the ICN. The nomenclatural
42
43 89 status of *Alexandrium* is discussed in Table 1.
44
45
46
47
48

49 90 Fossil-defined names are typically used by those who work primarily with the
50
51 91 cyst stage, for example in biostratigraphic age determinations, in documenting the
52
53 92 geographic distributions of modern cysts, or in helping to interpret past environmental
54
55
56
57
58
59
60

1
2
3 93 conditions, including climate. Non-fossil-defined names are used mainly by biologists,
4
5 94 who may have access to all stages of the life cycle and who have in the past mostly
6
7 95 focused on the motile stage(s). There is an understandable desire to integrate these two
8
9 96 taxonomic and nomenclatural systems, allowing information to flow more freely between
10
11 97 biological and geological realms (Ellegaard et al. 2018). However, the inevitable
12
13 98 problems with unifying this nomenclature (at least at generic and lower rank; Fensome et
14
15 99 al. 1993) have been long anticipated (e.g. Downie et al. 1961; Evitt and Davidson 1964,
16
17 100 p. 10–11; Evitt 1970, p. 38; Reid 1974; Dale 1983), and attempts to effect unification
18
19 101 (e.g. Harland 1982) have not been widely adopted.

20
21
22
23
24 102 In this article we evaluate the provisions of the ICN that support dual
25
26 103 nomenclature and investigate the origins of this duality. We then assess the practical
27
28 104 difficulties of unification and explore inconsistencies in nomenclature when binomials
29
30 105 are created that combine the names of fossil- with non-fossil taxa (Table 2).
31
32
33 106 Recommendations using dual nomenclature are offered to resolve ambiguities introduced
34
35 107 by these hybridized names, and a solution is provided regarding the fossil-genus
36
37 108 *Lingulodinium* Wall 1967 emend. Wall and Dale in Wall et al. 1973, which presently
38
39 109 contains both non-fossil and fossil-species. Full authorial attributions of taxonomic
40
41 110 names cited in the text are listed in Table 1. The ICN (Turland et al. 2018) includes a
42
43 111 glossary of nomenclatural terms, and Turland (2019) also contains helpful definitions.
44
45 112 For definitions of morphological terms, the reader is directed to Williams et al. (2000).
46
47 113 The abbreviation “Art.” refers to an article of the current ICN (Turland et al. 2018) unless
48
49 114 otherwise stated.

3 116
45 117 **2. The origins of dual nomenclature in dinoflagellates**
67
8 118
9

10 119 Living dinoflagellate resting cysts were first documented in the 19th century (noted in von
11
12 120 Stein 1878; illustrated e.g. in von Stein 1883; Penard 1891; Schilling 1891; Delage and
13
14 121 Herouard 1896). Biologists subsequently studied them from culture (Braarud 1945) and
15
16 122 in the plankton (e.g. Nordli 1951), and they were identified from sediment by the paleo-
17
18 123 and actuopalynologist Erdtman (1954). These early contributions by Nordli, Erdtman and
19
20 124 especially Braarud led the paleontologist Evitt (1961) to his breakthrough realization that
21
22 125 dinoflagellate cysts have a long and comprehensive geological record (Dale 2021). Evitt
23
24 126 (1961) recognized that many post-Paleozoic chorate organic-walled microfossils with
25
26 127 spines or processes, including the important genera *Hystrichosphaera* (now considered a
27
28 128 heterotypic synonym of *Spiniferites*), *Hystrichosphaeridium* and *Cannosphaeropsis*, were
29
30 129 in fact the chorate cysts of dinoflagellates (although he also considered many proximate
31
32 130 cysts to be fossilized motile stages – an error corrected in Evitt 1963, and Evitt and
33
34 131 Davidson 1964). Evitt and Davidson (1964) extended this knowledge with observations
35
36 132 of modern dinoflagellate cysts, and they discussed the potential complications arising
37
38 133 from the separate nomenclatures developing independently for both fossil cysts and
39
40 134 motile stages, as first recognized by Downie et al. (1961) and subsequently addressed by
41
42 135 Deflandre (1962).

43
44
45 136 By incubating a living cyst and identifying the emergent motile cell, Wall (1965)
46
47 137 directly linked the fossil cyst species *Spiniferites bentorii* (as *Hystrichosphaera bentorii*),
48
49 138 described from the Quaternary of the coastal plain of Israel (Rossignol 1964), to its
50
51
52
53
54
55
56
57
58
59
60

1
2
3 139 motile-defined equivalent, *Gonyaulax digitale*. Subsequent incubation studies by Wall
4
5 140 and Dale (1966) linked the fossil cyst species *Spiniferites bulloideus* (as
6
7 141 *Hystriosphera bulloidea*) from the Middle Miocene of Balcombe Bay, Australia
8
9 142 (Deflandre and Cookson 1955), to the motile-defined *Gonyaulax scrippsae*. They also
10
11 143 identified the prospective equivalencies of *Operculodinium centrocarpum* (as
12
13 144 *Baltisphaeridium centrocarpum*) and *Lingulodinium machaerophorum* (as
14
15 145 *Baltisphaeridium machaerophorum*), both from the Middle Miocene of Balcombe Bay,
16
17 146 Australia (Deflandre and Cookson 1955), with the motile-defined *Protoceratium*
18
19 147 *reticulatum* and *Lingulodinium polyedra* (as *Gonyaulax polyedra*), respectively.
20
21 148 Although some of the proposed equivalencies can now be challenged or revised (e.g. Gu
22
23 149 et al. 2021; Table 2), these and others studied later revealed that numerous dinoflagellates
24
25 150 described as fossils are represented by already-named living organisms (the “living
26
27 151 fossils” of Wall and Dale 1966): thus fossil and non-fossil taxonomies and their
28
29 152 corresponding nomenclatures were overlapping.

40 155 **3. ICN and fossil-taxa versus non-fossil taxa**

41
42 156
43
44 157 Dual nomenclature essentially requires only that separate names for fossil and non-fossil
45
46 158 taxa be allowed, as has long been the case, provided that *equivalence* (Head et al. 2016)
47
48 159 and not *synonymy* (a taxonomic decision influenced by conceptual considerations as
49
50 160 discussed in Subsection 3.2 below) is invoked. Dual nomenclature for algae, excepting
51
52 161 diatoms, is admissible under the current ICN, being supported by Arts. 1.2, 11.1, 11.7,
53
54
55
56
57
58
59
60

1
2
3 162 11.8, with Arts. 13.3 and 52.1 also relevant (Head et al. 2016; Head et al. 2024). The ICN
4
5 163 fundamentally distinguishes between non-fossil taxa and fossil-taxa (Art. 1.2), each of
6
7 164 which will have its own particular circumscription. Art. 11.1 states that “The use of
8
9 165 separate names is allowed for fossil-taxa that represent different parts, life-history stages,
10
11 166 or preservational states of what may have been a single organismal taxon or even a single
12
13 167 individual.” Key developments applicable to fossil and non-fossil dinoflagellate
14
15
16 168 nomenclature are discussed below and summarized in Table 3.

19 169 As an aside, the inadmissibility of dual nomenclature for diatoms under the ICN
20
21 170 may seem at odds with its availability for dinoflagellates when both algal groups have a
22
23 171 resting stage and a vegetative stage. The difference, however, is that the vegetative stage
24
25 172 in diatoms is geologically preservable, and this stage is most commonly studied in the
26
27 173 fossil record. Because the taxonomy of living diatoms is also based on the vegetative
28
29 174 stage, so extinct fossil-species based on the vegetative stage can be assigned to non-fossil
30
31 175 genera using morphological criteria alone. Fossil spores have long been neglected in
32
33 176 diatom studies (Suto 2004; Suto and Tanaki 2017) but, in parallel with dinoflagellates,
34
35 177 fossil-species based on spores cannot easily be integrated into the generic scheme for
36
37 178 non-fossil diatoms.

41
42 179

44 180 ***3.1. Historical development of plant fossil and algal nomenclature***

46
47 181 The naming of plant fossils long predates what was effectively the first botanical
48
49 182 code as adopted by the International Biological Congress in Paris in 1867 (the Paris
50
51 183 “Lois” or laws or rules; de Candolle 1867). The nomenclature of organs and fossils was
52
53 184 subsequently discussed, and a revised edition of the “Lois” (de Candolle 1883) explicitly

1
2
3 185 accepted that the rules also applied to plant fossils, although the Vienna Rules of 1906
4
5 186 (Briquet et al. 1906) were the first to acknowledge the special needs of fossils; these were
6
7 187 addressed in the Brussels Rules of 1912 (Briquet 1912). With the establishment of the
8
9 188 International Association of Plant Taxonomy (IAPT) at the 7th International Botanical
10
11 189 Congress in Stockholm in 1950 (Cowan and Stafleu 1982), each successive iteration of
12
13 190 the “Rules” was thereafter known as the “International Code of Botanical Nomenclature”
14
15 191 (ICBN). This was to change only in 2012, with the Melbourne Code (McNeill et al. 2012)
16
17 192 adopting the new title “International Code of Nomenclature for algae, fungi, and plants”
18
19 193 (ICN) in acknowledgement that the fungi in particular are not considered plants.

20
21
22
23
24 194 Of crucial significance was a growing awareness that the fragmentary nature of
25
26 195 plant fossils required taxonomic approaches that were different from living plants, and
27
28 196 separate nomenclatural rules have therefore evolved to meet these particular needs (Table
29
30 197 3). The Stockholm Code of 1952 (Lanjouw et al. 1952) introduced an Appendix on
31
32 198 fossils, which included the concepts of “organ-genera” to reflect the different preserved
33
34 199 parts of the plant and their modes of preservation, and “form-genera” as a small subset of
35
36 200 organ-genera containing species grouped superficially and not generically related in the
37
38 201 ordinary taxonomic sense (Cleal and Thomas 2010). The Montreal Code of 1961
39
40 202 (Lanjouw et al. 1961) defined the organ-genus as a genus assignable to a family, and a
41
42 203 form-genus as unassignable to a family and hence “artificial in varying degree”. The
43
44 204 concept of organ-genus was discontinued in the Leningrad Code of 1978 (Stafleu et al.
45
46 205 1978), and the “morphotaxon” was introduced in the St Louis Code of 2000 (Greuter et
47
48 206 al. 2000) as “a fossil taxon which, for nomenclatural purposes, comprises only the parts,
49
50 207 life-history stages, or preservational states represented by the corresponding
51
52
53
54
55
56
57
58
59
60

1
2
3 208 nomenclatural type” (Art. 1.2). This definition was restricted in the Vienna Code of 2006
4
5 209 (McNeill et al. 2006) to apply to a single part, life-history stage, or preservational state
6
7
8 210 (Art. 1.2, and its note 1). The morphotaxon concept was, however, considered too
9
10 211 restrictive and was discontinued in the Melbourne Code of 2012 in favour of the simpler
11
12 212 and more flexible concept of “fossil-taxon”. The term “fossil taxon” had first appeared in
13
14 213 the St Louis Code of 2000 for a name based on a fossil type (Art. 13.3), and more
15
16
17 214 prominently featured in the Vienna Code of 2006, in both cases without hyphenation.
18
19 215 The Melbourne Code introduced the hyphen, as “fossil-taxon”. Fossil-taxa can therefore
20
21 216 be regarded conceptually, with qualification, as the successor of organ-genera and form-
22
23 217 genera (Cleal and Thomas 2010), although it might be noted that all these concepts
24
25
26 218 effectively allowed fossils representing different life-history stages to bear separate
27
28
29 219 names, with clear relevance to fossil dinoflagellate nomenclature.

30
31 220 The Edinburgh Code of 1966 introduced the requirement of “stratigraphic
32
33 221 relations” at the site of original occurrence for fossil taxa, thus distinguishing them from
34
35 222 “Recent material” (Art. 13 note 3 in Lanjouw et al. 1966). “Recent” for the first time was
36
37
38 223 capitalized throughout, implying reference to the Holocene Epoch, as these terms were
39
40 224 being used interchangeably at that time. The Sydney Code of 1983 clarified the
41
42 225 relationship between “fossil” and “recent” (now lowercased) plants by referring to the
43
44 226 latter as “non-fossil” plants (Voss et al. 1983), and the Melbourne Code of 2012 saw the
45
46
47 227 elimination of “subfossil” which was introduced in the Stockholm Code of 1952 and had
48
49 228 never been defined. This unambiguously allowed cysts recovered from modern naturally
50
51 229 deposited sediments to be treated as fossils (Head 2003; Head et al. 2024; and Subsection
52
53
54 230 3.2 below).

1
2
3 231 Several starting dates of relevance for the valid publication of fossil-taxa and non-
4
5 232 fossil algal taxa introduced over successive editions of the Code are incorporated into the
6
7 233 present (Shenzhen) Code of 2018 (Turland et al. 2018): the article numbers that follow
8
9
10 234 are from this Code. The name of a new taxon of non-fossil algae published between 1
11
12 235 January 1958 and 31 December 2011, inclusive, must be accompanied by a Latin
13
14 236 description or diagnosis or by reference to such (Art. 44.1, introduced in the Paris Code
15
16 237 of 1956 [Lanjouw et al. 1956] and Melbourne Code of 2012). The name of a new fossil-
17
18 238 taxon published on or after 1 January 1996 must be accompanied by a Latin or English
19
20 239 description or diagnosis or by reference to such (Art. 43.1, introduced in the Tokyo Code
21
22 240 of 1994; Greuter et al. 1994); and the same is true for a new non-fossil taxon published
23
24 241 from 1 January 2012 (Art. 39.2, introduced in the Melbourne Code of 2012). Latin
25
26 242 therefore ceased to become a requirement for the diagnoses or descriptions of non-fossil
27
28 243 taxa from 1 January 2012 (this had been the case for fossil-taxa from 1 January 1996), a
29
30 244 decision met with spontaneous applause at the Nomenclature Section of the 18th
31
32 245 International Botanical Congress in Melbourne in 2011.

33
34
35
36
37 246 A name of a new species or infraspecific taxon of non-fossil algae, from 1 January
38
39 247 1958, must be accompanied by an illustration or figure showing the distinctive
40
41 248 morphological features of this taxon, or by a reference to such an illustration or figure
42
43 249 (Art. 44.2; introduced in the Paris Code of 1956). The valid publication of a name of a
44
45 250 new fossil-species or infraspecific fossil-taxon from 1 January 2001 requires the type
46
47 251 specimen to be identified among the validating illustrations (Art. 43.3; introduced in the
48
49 252 St Louis Code of 2000). The type of a name of a new non-fossil taxon at the rank of
50
51 253 species or below published before 2007 may be an illustration; but from 1 January 2007,
52
53
54
55
56
57
58
59
60

1
2
3 254 the type must be a specimen except where, in the case of a non-fossil microscopic
4
5 255 organism, preservation is technically difficult (Art. 40.4 and 40.5; introduced in the
6
7 256 Vienna Code of 2006). A type specimen of an algal taxon may be a culture preserved in a
8
9
10 257 metabolically inactive state (Art. 8.4; introduced in the St Louis Code of 2000); but from
11
12 258 1 January 2019, if a new name has such a type, this must be specified within the
13
14 259 protologue (Art. 40.8; introduced in the Shenzhen Code of 2018).

16
17 260 The first example of dual nomenclature in dinoflagellates appeared in the St.
18
19 261 Louis Code of 2000 (under Art. 11.7; the fossil-genus *Tuberculodinium* vs. the non-fossil
20
21 262 *Pyrophacus*), and the current Shenzhen Code contains a total of three such examples (in
22
23 263 Arts. 11.7 and 11.8; but see Head et al. 2024). Texts of the Laws, Rules and Codes noted
24
25 264 above are available online, showing successive changes to each version (van Rijckevorsel
26
27 265 2014–2020).

28
29
30
31 266

32 33 267 **3.2. Theoretical considerations**

34
35 268 The name of a fossil-taxon does not compete for priority with that of an
36
37 269 equivalent non-fossil taxon where it is not considered a synonym of that non-fossil taxon
38
39 270 (Art. 11.8) (Head et al. 2024). For example, Reid (1977) proposed the name *Votadinium*
40
41 271 *spinosum* for a fossil cyst he considered equivalent to the cyst of *Peridinium claudicans*
42
43 272 (now *Protoperidinium claudicans*) as illustrated by Wall and Dale (1968), who had
44
45 273 incubated this cyst type and identified the emergent theca (see Matsuoka and Head 2013,
46
47 274 for further discussion). Reid (1977) did not treat *Protoperidinium claudicans* as a
48
49 275 synonym and did not cite its holotype in the synonymy, which would have made the
50
51 276 name *Votadinium spinosum* superfluous and hence illegitimate (Art. 52.1). Nor did he
52
53
54
55
56
57
58
59
60

1
2
3 277 include motile-stage characteristics in his circumscription. Equivalence refers to “a noted
4
5 278 morphological similarity or identity between a fossil-taxon and a part or life-history
6
7
8 279 stage of a non-fossil taxon at the same rank where the names of these two taxa are not
9
10 280 considered synonyms” (Head et al. 2024). A synonym is “one of two or more names that
11
12 281 apply to the same taxon” (ICN glossary). The difference between equivalence and
13
14 282 synonymy rests upon that between paleontological and biological species concepts. A
15
16 283 fossil-species may closely resemble, or appear identical with, the morphology of a resting
17
18 284 cyst belonging to a named non-fossil species, thus allowing it to be considered
19
20 285 “equivalent” although not taxonomically identical (as required of synonyms). The latter
21
22 286 would require assumptions that all parts of the life cycle are the same and have remained
23
24 287 so perhaps over tens of millions of years. This issue is common to all plankton groups but
25
26 288 is exacerbated in dinoflagellates by the fact that non-fossil nomenclature is traditionally
27
28 289 based on the motile cell, which rarely fossilizes (see Section 3, above). According to
29
30 290 Principle 4 of the ICN, “Each taxonomic group with a particular circumscription,
31
32 291 position, and rank can bear only one correct name, the earliest that is in accordance with
33
34 292 the rules, except in specified cases.” But this does not apply to a non-fossil species and its
35
36 293 equivalent fossil-species as the circumscriptions are different even when the non-fossil
37
38 294 species is circumscribed to include a description of the cyst. Accordingly, *Votadinium*
39
40 295 *spinosum* as a fossil-defined species can be used as the correct name for the cyst.
41
42 296 However, should *Votadinium spinosum* and *Protoperidinium claudicans* be considered
43
44 297 conspecific and therefore synonymous, then *Protoperidinium claudicans* would be the
45
46 298 correct name because it is defined by a non-fossil type and so has priority over that of a
47
48 299 fossil-species (Art. 11.8). It should be emphasized that *equivalence* expresses a
49
50
51
52
53
54
55
56
57
58
59
60

1
2
3 300 relationship between fossil-defined and non-fossil defined taxa, with the fossil (usually
4
5 301 cyst) morphology operating as the intermediary.
6

7
8 302 Dual and unified nomenclature are equally available under the ICN allowing the
9
10 303 practitioner to exercise choice, which reflects separate taxonomic approaches. The
11
12 304 purpose of the ICN is not to restrict such approaches but rather to facilitate their
13
14 305 nomenclatural expression (Head et al. 2024). The suggestion by Ellegaard et al. (2018 p.
15
16 306 229) that dual nomenclature can be removed from formal nomenclature is not an option
17
18 307 while practitioners wish to use it; the decision to use a dual or unified approach is thus a
19
20 308 taxonomic rather than a nomenclatural one. Nonetheless, Elbrächter et al. (2023)
21
22 309 proposed changes to the ICN that would diminish its support for dual nomenclature.
23
24 310 Their proposals have been critiqued by Head et al. (2024).
25
26
27

28 311 This raises the question of how a fossil- and a non-fossil taxon are distinguished.
29
30 312 A fossil-taxon (diatoms excepted) is defined by a fossil nomenclatural type (Art. 1.2),
31
32 313 which must be an actual specimen (Art. 8.5). For a fossil dinoflagellate taxon, this is
33
34 314 assumed to be a resting cyst in all but a few cases. The ICN distinguishes fossil- from
35
36 315 non-fossil material “by stratigraphic relations at the site of original occurrence”.
37
38 316 Importantly, “in cases of doubtful stratigraphic relations ... provisions for non-fossil taxa
39
40 317 apply” (Art. 13.3). Effectively, the principle of superposition should apply, which is
41
42 318 indeed the case for most naturally occurring marine sediments. Bioturbation, which is
43
44 319 common in most marine sediments, may blur stratigraphic relations but on a broad scale
45
46 320 does not completely destroy them. There is a long tradition of treating cysts from surface
47
48 321 sediments as fossils, whether these sediments are from nearshore grab samples or from
49
50 322 the tops of deep-sea cores. For example, taxa described from surface sediments around
51
52
53
54
55
56
57
58
59
60

1
2
3 323 the coast of the British Isles by Reid (1974, 1977) are widely accepted as fossil-taxa.
4
5 324 They include the genera *Ataxiodinium*, *Dubridinium*, *Trinovantedinium*, *Votadinium* and
6
7 325 *Xandarodinium*, and the species *Ataxiodinium choane*, *Brigantedinium auranteum*,
8
9
10 326 *Brigantedinium majusculum* (but see below for the genus *Brigantedinium*), *Dubridinium*
11
12 327 *caperatum*, *Dubridinium cassiculum*, *Dubridinium cavatum*, *Dubridinium ulsterum*,
13
14 328 *Spiniferites delicatus*, *Spiniferites elongatus*, *Spiniferites lazus*, *Votadinium calvum*,
15
16 329 *Votadinium spinosum*, and *Xandarodinium xanthum* (Mertens et al. 2020; Van
17
18 330 Nieuwenhove et al. 2020).

19
20
21 331 In reality, such surface sediment samples may contain living as well as dead/fossil
22
23 332 cysts, and viable cysts have been found in sediments as old as 100 years (Ellegaard and
24
25 333 Ribeiro 2018). The definition of a fossil under Art. 13.3 is also discussed by Head et al.
26
27 334 (2024). The type specimen of a non-fossil taxon may have been alive when collected,
28
29 335 even though it cannot be living when serving as type material (except under specific
30
31 336 circumstances; Art. 8.4). In contrast, it is reasonable to require of a specimen treated
32
33 337 nomenclaturally as a fossil that it was not demonstrably living at the time of collection.
34
35 338 This question does not arise if the specimen is an empty germinated cyst but becomes
36
37 339 theoretically pertinent if it has cell contents. In practice, the usual chemical processing of
38
39 340 surface marine sediment using HCl and HF will kill any living cysts, so it will not be
40
41 341 known whether the cyst was dead when collected. It is therefore simply assumed for
42
43 342 nomenclatural purposes that cysts having undergone palynological processing were dead
44
45 343 at the time of collection. For example, *Spiniferites elongatus* and *Echinidinium karaense*
46
47 344 have holotypes containing degraded cell contents yet are treated as fossil-taxa. It would
48
49 345 serve no good purpose to treat them otherwise. In the case of a thin-walled cyst, it may
50
51
52
53
54
55
56
57
58
59
60

1
2
3 346 indeed be desirable for the holotype to have cell contents because these (especially the
4
5 347 cellulosic endospore) keep the cyst wall inflated, allowing its morphological details to be
6
7
8 348 studied more easily. The holotypes of *Echinidinium karaense* and *Islandinium*
9
10 349 *brevispinosum* provide examples of this, and a specimen of *Islandinium minutum* with
11
12 350 cell contents (pl. 1, figs. d–i of Head et al. 2001) was used to elucidate the unusual
13
14 351 archeopyle style in this common arctic species. Dinoflagellate cysts with preserved
15
16
17 352 endospores are known from Middle Pleistocene deposits as old as 767 ka (fig. 7b, g in
18
19 353 Balota et al. 2021).

20
21 354 A non-fossil species is defined by a non-fossil nomenclatural type. The type can
22
23 355 be either a specimen or an illustration (Art. 8.1), although for algae from 1 January 2007
24
25 356 an illustration cannot be used (Art. 40.4) unless “there are technical difficulties of
26
27 357 specimen preservation or if it is impossible to preserve a specimen that would show the
28
29 358 features attributed to the taxon by the author of the name” (Art. 40.5). In the case of a
30
31 359 specimen, the organism is not usually living (Art. 8.4), as noted above. Traditionally,
32
33 360 non-fossil dinoflagellate species have been typified using an illustration of the motile
34
35 361 stage. However, Ellegaard et al. (2002) typified the name *Gonyaulax baltica* using a cyst
36
37 362 from culture rather than a motile stage. It is not clear whether the holotype is the cyst
38
39 363 itself (a curated dead specimen on a scanning electron microscope [SEM] stub) or the
40
41 364 SEM illustration of it (fig. 3A in Ellegaard et al. 2002), but either is acceptable under the
42
43 365 ICN because publication predates 1 January 2007. The observations were from a living
44
45 366 unialgal culture (one grown from a single wild resting cyst), and this appropriately
46
47 367 allowed the protologue (everything associated with a name at its valid publication) to
48
49 368 include information on both the cyst and motile stage. In typifying *Gymnodinium nolleri*,

1
2
3 369 Ellegaard and Moestrup (1999) used a fixed (dead) and embedded sample of unialgal
4
5 370 culture which presumably included cysts as well as motile cells, an acceptable holotype
6
7 371 under the ICN (Art. 8.2). Their figure 1 illustrates both cyst and motile stages of
8
9
10 372 *Gymnodinium nolleri* from this unialgal culture which, now preserved, serves as the
11
12 373 holotype.
13
14
15 374

16 17 375 **3.3. Problematic cases**

18
19 376 In defining the non-fossil *Gonyaulax ellegaardiae* from Izmir Bay, Turkey,
20
21 377 Mertens et al. (2015) attempted to establish a dual nomenclatural relationship between it
22
23 378 and the fossil-species *Spiniferites pachydermus*, the latter having been described from the
24
25 379 subsurface Pleistocene or Holocene of the coastal plain of Israel (as *Hystrichosphaera*
26
27 380 *furcata* var. *pachyderma* in Rossignol et al. 1964). Mertens et al. (2015) selected two
28
29 381 illustrations (their figs. 2 and 5a–i) as the holotype. Their fig. 5a–i illustrates an incubated
30
31 382 cyst from which a thecate cell (their fig. 2) emerged. While it is sound biological practice
32
33 383 to illustrate both stages of the life cycle, only one illustration can be used as a holotype;
34
35 384 moreover, from 1 January 2007 only a specimen can be designated unless there are
36
37 385 technical difficulties with specimen preservation (Art. 40.5). The specimens illustrated as
38
39 386 types were not preserved (Mertens et al. 2015, p. 564) owing to such difficulties. Here
40
41 387 we designate fig. 2 of Mertens et al. (2015) as the holotype of *Gonyaulax ellegaardiae*
42
43 388 Mertens, Aydin, Takano, Yamaguchi and Matsuoka in Mertens et al. (2015), completing
44
45 389 requirements for valid publication. This illustration is of a specimen of the motile stage.
46
47 390 Although Mertens et al. (2015) considered *Gonyaulax ellegaardiae* to be equivalent to
48
49 391 *Spiniferites pachydermus*, this relationship appears to be incorrect and a new fossil-

1
2
3 392 species will be formally proposed (MJH and KNM in prep.). A dual nomenclatural
4
5 393 approach allows both species, each typified by its own holotype, to remain as useful
6
7 394 individual concepts despite their problematic relationship.
8
9

10 395 Reid (1974, 1977) established numerous fossil-species that were typified using
11
12 396 cyst specimens recovered mostly from intertidal surface sediments around the British
13
14 397 Isles, as noted in Subsection 3.2 above. The status of these holotypes as fossils is widely
15
16 398 accepted on the basis that they were obtained from naturally deposited sediment where
17
18 399 the principle of superposition broadly applies. In contrast, the genus *Echinidinium* and its
19
20 400 holotype species *Echinidinium granulatum* were typified by a cyst recovered from a
21
22 401 sediment trap (Zonneveld 1997) where stratigraphic relations could not be reasonably
23
24 402 inferred (Head 2003). The genus and its holotype species were therefore to be treated as
25
26 403 non-fossil taxa (Head 2003). The genus and selected species were validated only when
27
28 404 Head et al. (2001) provided Latin diagnoses, as then required for non-fossil taxa. Other
29
30 405 species were validated by Mertens et al. (2020).
31
32
33
34

35 406 A similar example involves the genus *Brigantedinium* and its holotype species
36
37 407 *Brigantedinium simplex*. The type specimen, known then as *Chytroeisphaeridia*
38
39 408 *simplicia*, was recovered from a settling tray at the bottom of the aquarium at Woods
40
41 409 Hole Oceanographic Institution (Wall 1965). This specimen cannot be treated as a fossil
42
43 410 because sediments accumulated in such settling trays are prone to disturbance and the
44
45 411 trays themselves are periodically emptied. Stratigraphic relations are therefore doubtful at
46
47 412 best, and where doubt exists provisions for non-fossil taxa apply (Art. 13.3). However,
48
49 413 because these taxa had been proposed as fossil-taxa, no Latin diagnoses were provided.
50
51
52
53
54
55
56
57
58
59
60

1
2
3 414 The names were only validly published when Lentin and Williams (1993, p. 67) supplied
4
5 415 Latin diagnoses, as discussed in Subsection 6.2 below.
6
7

8 416
9

10 417
11

12 418 **4. Obstacles to a unified nomenclature**

13

14 419
15

16
17 420 Wall and Dale (1968) showed that cysts corresponding to three fossil-genera, now known
18
19 421 as *Nematosphaeropsis*, *Spiniferites*, and *Tectatodinium*, all give rise to motile stages
20
21 422 assignable to a single theca-defined non-fossil species complex that includes *Gonyaulax*
22
23 423 *spinifera*. It is now accepted that at least six such genera, *Ataxiodinium*, *Bitectatodinium*,
24
25 424 *Impagidinium*, *Nematosphaeropsis*, *Spiniferites* and *Tectatodinium*, are produced by the
26
27 425 non-fossil species *Gonyaulax spinifera* and its allies (Head 1996) including a species
28
29 426 closely related to *Gonyaulax polygramma* in the case of *Ataxiodinium choane* (Mertens et
30
31 427 al. 2017a). Subsuming these six fossil-genera and their contained species into a single
32
33 428 non-fossil genus would result in an unacceptable loss of detail within the fossil-defined
34
35 429 classification. Considerable progress in expanding and refining cyst-theca relationships
36
37 430 within the genus *Gonyaulax* has been made since the pioneering work of Wall and Dale
38
39 431 (Gu et al. 2021, 2022, 2023, and references therein). Recent molecular phylogenetic
40
41 432 studies confirm the attribution of these fossil-genera to the non-fossil genus *Gonyaulax*,
42
43 433 but the studies demonstrate that the fossils are polyphyletic, with species of
44
45 434 *Tectatodinium*, *Bitectatodinium*, *Ataxiodinium* and *Impagidinium* intermingling with
46
47 435 those of *Spiniferites* in phylogenetic trees (Gu et al. 2021; Fig. 1). These results make any
48
49 436 efforts to integrate the fossil-genera with the genus *Gonyaulax* or indeed with its four
50
51
52
53
54
55
56
57
58
59
60

1
2
3 437 subgenera proposed by Kofoid (1911; *Gonyaulax*, *Fusigonyaulax*, *Steiniella*,
4
5 438 *Acanthogonyaulax*) very complicated. In general, the motile stage of *Gonyaulax* has a
6
7 439 more conserved morphology than that of its cyst counterparts, although small differences
8
9 440 in motile stage morphology that might allow placement in other genera have been noted
10
11 441 in some species, including *Gonyaulax polygramma* and *Gonyaulax geomunensis* (Kim et
12
13 442 al. 2023) and *Gonyaulax hyalina* (Escalera et al. 2018; but see Carbonell-Moore and
14
15 443 Mertens 2019).

16
17 444 A similar number of fossil-defined genera has been assigned to the large non-
18
19 445 fossil genus *Protoperidinium*. Harland (1982) attempted to integrate these fossil-genera
20
21 446 by reassigning them as sections of the genus *Protoperidinium*. However, the resulting
22
23 447 four-element name (genus, subgenus, section, species) while informative was an
24
25 448 unwieldy solution not adopted by the community (see Ellegaard et al. 2018 for further
26
27 449 discussion). This community includes a large and active group of
28
29 450 palynologists/actuopalynologists working on fossil dinoflagellate cysts as well as many
30
31 451 working on relationships with motile forms and utilising genetic techniques on cysts and
32
33 452 motile forms. The various sections of *Protoperidinium* conform to a certain extent with
34
35 453 the molecular phylogenies for this genus, although some are polyphyletic (Mertens et al.
36
37 454 2017b). More data are certainly needed before a thorough revision of the genus
38
39 455 *Protoperidinium* is possible.

40
41 456 Another difficulty emerges when a fossil-genus contains both extant and extinct
42
43 457 species. For example, the fossil-genus *Bitectatodinium* is typified by the holotype, a
44
45 458 fossil, of the extant *Bitectatodinium tepikiense*. This species had been linked by
46
47 459 incubation studies (Lewis et al. 2001) to the non-fossil *Gonyaulax digitale*. This
48
49
50
51
52
53
54
55
56
57
58
59
60

1
2
3 460 relationship is now known to be in error, although cysts assignable to *Bitectatodinium*
4
5 461 *tepiense* are possibly produced by a thecal morphotype from the Faeroe Islands that was
6
7 462 misidentified by Kofoid (1911) as *Gonyaulax digitale* (Gu et al. 2021). The link to
8
9 463 *Gonyaulax* is nonetheless not questioned, but *Bitectatodinium* cannot be subsumed or
10
11 464 synonymized with *Gonyaulax* because *Bitectatodinium* also contains several extinct
12
13 465 species for which the motile stage will likely never be known. Also, a molecular
14
15 466 phylogeny shows *Bitectatodinium tepicense* embedded in the genus
16
17 467 *Gonyaulax/Spiniferites* (Gu et al. 2021; Fig. 1). The genus *Bitectatodinium* is therefore
18
19 468 retained primarily for practical reasons and, as presently circumscribed, it does not
20
21 469 represent an evolutionary entity distinct from the large fossil-genus *Spiniferites*.

22
23
24
25
26 470 The demonstration that dinoflagellate cyst distributions in modern marine
27
28 471 sediments are strongly influenced by climate (Williams 1965, 1971) has led to the
29
30 472 systematic mapping of cysts throughout the world's oceans (e.g. Wall et al. 1977; Rochon
31
32 473 et al. 1999; Zonneveld et al. 2013; de Vernal et al. 2001, 2020) and an increasing use of
33
34 474 dinoflagellate cysts for quantitative as well as qualitative paleoclimatic reconstructions,
35
36 475 especially in mid- and high latitudes. This has led to a large and expanding literature on
37
38 476 Quaternary dinoflagellate cysts (Van Nieuwenhove et al. 2020a, and references therein).
39
40 477 The fossil-defined names used in the paleoenvironmental literature are now deeply
41
42 478 entrenched, imparting a natural resistance to nomenclatural unification even when the
43
44 479 motile stage eventually becomes known. A similar argument may be made regarding the
45
46 480 use of fossil-defined names in the literature dealing with the older fossil record. The
47
48 481 taxonomy and nomenclature of organic-walled dinoflagellate cysts throughout their
49
50 482 Triassic to Quaternary fossil record (Riding et al. 2023) is deeply integrated, and has a
51
52
53
54
55
56
57
58
59
60

1
2
3 483 long history extending into the 19th century (e.g. Ehrenberg 1837; Mantell 1850, p.191).
4
5 484 Although most fossil dinoflagellate cyst genera are now extinct, a few extend back tens,
6
7 485 or even hundreds of millions of years. An example is *Spiniferites*, which, through its
8
9 486 perhaps 120-million-year history, has accommodated more than 100 species (Fensome et
10
11 487 al. 2019): it is unknowable whether the motile equivalent of most of these species would
12
13 488 be assignable to *Gonyaulax*.
14
15

16
17 489 There may also be uncertainty in cyst-motile equivalencies, as with *Gonyaulax*
18
19 490 *digitale*, which has been linked both to *Spiniferites bentorii* by Wall (1965), Wall and
20
21 491 Dale (1967, p. 352) and Dodge (1989, p. 283) and to *Bitectatodinium tepikiense* by Lewis
22
23 492 et al. (2001); it is now known to be linked to neither (Gu et al. 2021; Table 2). While such
24
25 493 ambiguities are usually the result of uncertainty in the identification of the non-fossil
26
27 494 species, they are avoided by continuing to use fossil-defined names for the cysts.
28
29
30 495 However, the obstacle of uncertain cyst-motile equivalence is diminishing. Molecular
31
32 496 genetics now provides an excellent and increasingly affordable tool for identifying
33
34 497 species with greater certainty than by relying exclusively on morphological characters.
35
36 498 Molecular approaches can be used to link the motile stage definitively with the cyst.
37
38 499 Establishing correct equivalencies in combination with ribotyping is important as these
39
40 500 approaches are intrinsic to DNA databases used in metabarcoding such as PR² (Guillou et
41
42 501 al. 2013) and SILVA (Quast et al. 2013). Cultures of *Gonyaulax*, for instance, display
43
44 502 enormous variations and aberrations that make unambiguous identification of species
45
46 503 often difficult without such genetic characterization. Fossil-defined taxonomies therefore
47
48 504 should adapt where practicable to incorporate these new advances. In some cases,
49
50 505 however, neither cyst nor thecal morphology adequately reflect the diversity revealed in
51
52
53
54
55
56
57
58
59
60

1
2
3 506 molecular genetics. For example, *Protoceratium reticulatum* produces cysts that are
4
5 507 commonly reported in Quaternary sediments globally as *Operculodinium centrocarpum*
6
7 508 sensu Wall and Dale (1966). Small differences in the internal transcribed spacer
8
9
10 509 ribosomal DNA (ITS rDNA) sequences in *Protoceratium reticulatum* have revealed what
11
12 510 appears to be cryptic speciation, with ribotypes not being distinguishable by either cyst or
13
14 511 thecal morphology (Wang et al. 2019). Genetic drift over geological time, which may not
15
16 512 be expressed in the cyst morphology, adds further complexity in understanding the
17
18
19 513 relationships between fossil and modern taxa. A final caveat is that any molecular
20
21 514 approach assumes that the motile stage was correctly identified at the outset, but if it is
22
23
24 515 not then the genetic sequence will be linked to the wrong species. The same is true of a
25
26 516 cyst, but such errors in identification are more contained when using dual nomenclature.

27
28
29 517

30 518 **5. Conceptual underpinning of dual nomenclature**

31
32
33 519

34
35 520 Conceptual as well as practical issues underlie the difficulties in uniting fossil
36
37 521 with non-fossil cyst nomenclatures. Non-fossil names are traditionally based on
38
39 522 classifications centred on the morphology of the motile cell, but increasingly incorporate
40
41 523 all elements of the life cycle including the cyst and may include molecular (genetic)
42
43 524 information, striving for integrative taxonomy (Dayrat 2005). Indeed, such approaches
44
45 525 can reveal weaknesses in exclusively morphology-based taxonomies. For example, five
46
47 526 non-fossil species of the important *Alexandrium tamarense* species complex – *A.*
48
49 527 *australiense*, *A. catenella*, *A. mediterraneum*, *A. pacificum*, and *A. tamarense* – could not
50
51 528 be reliably distinguished using morphological criteria alone, although collectively they
52
53
54
55
56
57
58
59
60

1
2
3 529 partitioned into five cryptic species based on phylogenies using multiple regions in the
4
5 530 rDNA operon (John et al. 2014). In order to stabilize the nomenclature, John et al. (2014)
6
7
8 531 provided emended and new species circumscriptions that combine morphological and
9
10 532 molecular information with details of toxicity (see also Litaker et al. 2018).

11
12 533 Extinct species on the other hand are based exclusively on morphological
13
14 534 attributes of the cyst, except for rare cases (e.g. the motile and other stages of
15
16
17 535 *Succiniperidinium inopinatum* preserved in mid-Cretaceous amber; Masure et al. 2013).
18
19 536 The relative importance of each attribute should nonetheless be influenced by any known
20
21
22 537 biological affinity to produce as “natural” a classification as possible. One potential
23
24 538 example is the fossil-genus *Selenopemphix*, its holotype species *Selenopemphix*
25
26 539 *nephroides* having been described from the Oligocene of Germany (Benedek 1972). This
27
28 540 cyst-defined species occurs in modern sediments and seems to be produced by the non-
29
30
31 541 fossil *Protopteridinium subinerme* (Rochon et al. 1999). The fossil-genus *Multispinula*
32
33 542 was considered synonymous with and junior to *Selenopemphix* by Matsuoka (1985c) and
34
35 543 Head (1993). Its holotype species *Multispinula quanta* (now *Selenopemphix quanta*) was
36
37
38 544 described from modern sediments of the Persian Gulf (Bradford 1975), and it seems to be
39
40 545 equivalent to the non-fossil species *Protopteridinium conicum* (although more research on
41
42 546 this relationship is needed; Matsuoka and Head 2013). Molecular phylogenetic analysis
43
44
45 547 of *Selenopemphix nephroides* and its equivalent *Protopteridinium subinerme* has not yet
46
47 548 been undertaken, but that of the morphologically similar *Selenopemphix undulata*
48
49 549 described from late Quaternary sediments of the Pacific Ocean (Verleye et al. 2011)
50
51 550 places it in a different clade from that of *Protopteridinium conicum* (putatively equivalent
52
53
54 551 to *Selenopemphix quanta*) (fig. 3 of Mertens et al. 2017b; Fig. 2). *Selenopemphix* as

1
2
3 552 presently circumscribed might therefore be polyphyletic, raising the question of whether
4
5 553 *Multispinula* and *Selenopemphix* should be treated as separate fossil-genera (Mertens et
6
7
8 554 al. 2017b). If such separation were justified, attention could focus on the offset of the
9
10 555 archeopyle (epicystal asymmetry) and details of ornamentation. Molecular phylogeny
11
12 556 therefore allows new questions to be asked with respect to morphology-based cyst
13
14
15 557 taxonomy. The cyst-defined non-fossil genus *Brigantedinium* is certainly polyphyletic,
16
17 558 and potential solutions are discussed below.

19 559 Nonetheless, an extinct fossil-species, with rare exception, can only be defined by
20
21 560 the morphological features of a single stage in the life cycle. There is no certainty that an
22
23
24 561 extant fossil-species in the geological past produced a motile stage identical to its modern
25
26 562 counterpart. This is especially true of extant fossil-species with long stratigraphic ranges,
27
28 563 such as *Tectatodinium pellitum* and *Lingulodinium machaerophorum*, both of which
29
30
31 564 evolved in the Paleocene (Head and Nøhr-Hansen 1999, and Heilmann-Clausen 1985,
32
33 565 respectively).

35 566 *Dapsilidinium pastielsii* was described from the Lower Eocene of southeastern
36
37 567 England (Davey and Williams 1966) and had its inception in the Early Paleocene or
38
39
40 568 before. Living cysts equated with this fossil-species have been incubated to yield a motile
41
42 569 stage belonging to an as-yet-unnamed non-fossil species and genus (Mertens et al. 2014).
43
44
45 570 Following the practice of dual nomenclature, and pending further study, this non-fossil
46
47 571 species will be formally described as new, based on all aspects of its life cycle and
48
49 572 molecular characterization, and typified by a motile cell or its illustration. It will bear a
50
51 573 new name and be assigned to a non-fossil genus. *Dapsilidinium pastielsii* will then be
52
53
54 574 considered equivalent to, but not conspecific with, this new non-fossil species.

1
2
3 575 Applying a non-fossil name to a Paleocene specimen would assume that because
4
5 576 the cyst morphology has not changed significantly over ~60 million years, its motile
6
7 577 stage has not changed either, when instead it might be a different biological species
8
9
10 578 retaining conservative cyst morphological features. This of course is true of any living
11
12 579 group with a fossil record, but in dinoflagellates the geologically preservable cyst
13
14 580 (usually assumed to be a hypnozygotic resting stage) is only one part of the life cycle, and
15
16 581 the part used historically in non-fossil taxonomy and nomenclature is the motile stage.
17
18
19 582 The cyst itself provides the overlap and point of connection between these different but
20
21 583 complementary biological (entire life cycle) and paleontological concepts (Fig. 3).
22
23

24 584 Because dual nomenclature reflects actual differences in taxonomic criteria
25
26 585 between fossils and non-fossils (cyst alone vs. motile stage and potentially cyst) it is
27
28 586 possible to determine equivalencies at the species level but not between genera.
29
30
31 587 Nonetheless, at the suprageneric level, which relies primarily on tabulation, as reflected
32
33 588 both in fossils (to varying degrees) and non-fossils, the two taxonomic systems can be
34
35 589 successfully aligned (e.g., Fensome et al. 1993).
36
37

38 590 In summary, dual nomenclature (and its underlying dual classification) is
39
40 591 considered a practical and conceptually sound approach in handling organic-walled cyst-
41
42 592 producing dinoflagellates. However, as with any other approach, consistency in
43
44 593 application is desirable, and dual nomenclature is a work in progress. Many modern cyst
45
46 594 morphotypes are not yet integrated into a fossil cyst classification scheme at generic or
47
48 595 lower rank and have only a non-fossil name. Some have fossil names but are not yet
49
50 596 linked to a non-fossil species. Others have hybridized names, such as when a fossil name
51
52 597 is attributed or transferred to a non-fossil genus. These variants all introduce practical and
53
54
55
56
57
58
59
60

1
2
3 598 conceptual difficulties that require clarifying and resolving. Examples, with potential
4
5 599 solutions where available, are discussed below.
6
7

8 600

9
10 601

11
12 602 **6. Nomenclatural hybrids in dual nomenclature**
13

14 603

15
16
17 604 ***6.1. A non-fossil cyst-typified species assigned to a fossil-genus***
18

19 605

20
21 606 *Nematosphaeropsis labyrinthus* was initially described from the plankton off the Faeroe
22
23 607 Islands by Ostenfeld (1903). Ostenfeld assigned his new species to the green algal
24
25 608 prasinophyte genus *Pterosperma*, although his line drawings and certainly later
26
27 609 observations by, for example, Reid (1974), support the contention that the species is a
28
29 610 trabeculate dinoflagellate cyst. Reid (1974) transferred this species to the fossil-genus
30
31 611 *Nematosphaeropsis*. Although a common cyst in modern North Atlantic sediment, its
32
33 612 thecal equivalence has not yet been determined with certainty. If the motile stage, when
34
35 613 known, can be attributed to a species named before that of Ostenfeld's species (1903), the
36
37 614 epithet *labyrinthus* will become a junior heterotypic synonym and therefore unavailable.
38
39 615 If the motile stage has not been named or was named after Ostenfeld's species, it will
40
41 616 take the epithet *labyrinthus* although the species would then be transferred to the
42
43 617 appropriate non-fossil genus, presumably *Gonyaulax*. Either way, the name
44
45 618 *Nematosphaeropsis labyrinthus* will be rendered unavailable for this important cyst
46
47 619 species.
48
49
50
51
52
53
54
55
56
57
58
59
60

1
2
3 620 An additional question is whether *Nematosphaeropsis labyrinthus* is equivalent to
4
5 621 *Nematosphaeropsis lemniscata*, described from the Upper Miocene of the Bering Sea
6
7 622 (Bujak 1984), as discussed in Head and Wrenn (1992) and by Rochon et al. (1999).
8
9 623 Modern cysts attributed to *Nematosphaeropsis labyrinthus* have been reported with
10
11 624 exclusively gonal processes (Reid et al. 1974; Van Nieuwenhove et al. 2020b) whereas
12
13 625 intergonal processes, identified by bifurcate process terminations, may also be present in
14
15 626 *Nematosphaeropsis lemniscata* (Bujak 1984). Bujak (1984) used relatively harsh
16
17 627 chemical processing treatments, and his microscope slides were prepared using a
18
19 628 synthetic mountant in a procedure that flattens delicate specimens. The original type
20
21 629 material may not therefore be helpful, and new material from the type stratum should be
22
23 630 examined. If *Nematosphaeropsis labyrinthus* and *Nematosphaeropsis lemniscata* indeed
24
25 631 prove morphologically equivalent, then *Nematosphaeropsis lemniscata* would become
26
27 632 the fossil-defined equivalent name for the non-fossil species we now call
28
29 633 *Nematosphaeropsis labyrinthus*. This would potentially allow dual nomenclature to
30
31 634 operate but again ultimately with the loss of the name *Nematosphaeropsis labyrinthus*.
32
33
34
35
36
37

38 635 Names normally unavailable due to strict application of the rules can be
39
40 636 conserved (retained) if such an action would best serve nomenclatural stability (Arts. 14.1
41
42 637 and 14.2). If the name *Nematosphaeropsis labyrinthus* is to continue being used into the
43
44 638 future following a tradition initiated by Reid in 1974, it will require conservation to that
45
46 639 of a fossil-species by the selection of a new (fossil) type (Art. 14.9). The equivalent non-
47
48 640 fossil stage when subsequently identified, if unassignable to an existing species, would be
49
50 641 described as a new species and placed in a non-fossil genus. *Nematosphaeropsis*
51
52
53
54
55
56
57
58
59
60

1
2
3 642 *lemniscata*, upon reexamination of topotype material, would be a junior heterotypic
4
5 643 synonym or a distinct species depending on the outcome.
6

7
8 644 Conservation of the name *Nematosphaeropsis labyrinthus* with a new (fossil) type
9
10 645 would initially require submission of a formal proposal to the journal *Taxon* whereupon
11
12 646 the International Association for Plant Taxonomy (IAPT) Permanent Nomenclature
13
14 647 Committee for Fossils would be called upon to provide a recommendation. The proposal
15
16 648 would ultimately require approval by the IAPT General Committee and final ratification
17
18
19 649 by the Nomenclature Section of an International Botanical Congress (e.g. McNeill et al.
20
21 650 2018; Carbonell-Moore 2018; Wilson 2023; and see Turland 2019, p. 86, 87).
22
23

24 651

25
26 652

27
28 653 **6.2. A non-fossil genus treated as if a fossil-genus**
29

30
31 654

32
33 655 The genus *Brigantedinium* was established by Reid (1977) with its nomenclatural type
34
35 656 the holotype of *Brigantedinium simplex*. This species was initially proposed under the
36
37 657 name *Chytroeisphaeridia simplicia* by Wall (1965), and its holotype was recovered from
38
39 658 a settling tray at the bottom of the aquarium at Woods Hole Oceanographic Institution
40
41
42 659 (Wall 1965). This specimen therefore cannot be treated as a fossil as it lacks stratigraphic
43
44 660 relations (Art. 13.3), even though it is an empty cyst and was not demonstrably living at
45
46 661 the time of collection (see Subsection 3.1, above). (The genus name *Chytroeisphaeridia*
47
48 662 is based on a [Jurassic] gonyaulacacean cyst and hence is not appropriate for a
49
50 663 protoperidiniacean species.)
51
52
53
54
55
56
57
58
59
60

1
2
3 664 As a non-fossil, this species at the time of publication was required to have a
4
5 665 Latin diagnosis, and because it was not provided by Wall (1965) the name was not
6
7 666 validly published. In addition, Reid (1977) did not provide a Latin diagnosis for his
8
9
10 667 *Brigantedinium* although this was required for a non-fossil genus. In fact, *Brigantedinium*
11
12 668 and *Brigantedinium simplex* were not validly published until Lentin and Williams (1993,
13
14 669 p. 67) provided Latin diagnoses and complete citations for them (Fensome et al. 2019). It
15
16 670 remains that both the name of the genus *Brigantedinium* and that of its holotype species,
17
18 671 *Brigantedinium simplex*, are defined by a non-fossil type specimen. Seven fossil-species
19
20 672 have since been assigned to *Brigantedinium* (Fensome et al. 2019), representing another
21
22 673 category of hybridized names (see Subsection 6.4).
23
24
25

26 674 *Brigantedinium simplex* has been identified by excystment studies as the cyst of
27
28 675 the non-fossil species *Protoperidinium conicoides* (Wall and Dale 1968; Head 1996).
29
30 676 Because both names are defined by non-fossil types, they compete for priority and
31
32 677 *Protoperidinium conicoides* becomes the senior heterotypic synonym. The genus
33
34 678 *Brigantedinium* then becomes a junior heterotypic synonym of *Protoperidinium*. The
35
36 679 complication is that *Brigantedinium* is an ecologically important Quaternary cyst genus
37
38 680 (de Vernal et al. 2020) represented by eight species including *Brigantedinium simplex*
39
40 681 (Mertens et al. 2020). Of these, seven are typified by specimens from ocean-floor
41
42 682 sediment and are treated as fossils. Hence a situation emerges where fossil-defined
43
44 683 species are assigned to a non-fossil defined genus that is now a junior heterotypic
45
46 684 synonym and therefore unavailable.
47
48
49
50

51 685 The least disruptive solution *prima facie* would be for the generic name
52
53 686 *Brigantedinium* and that of its holotype species, *Brigantedinium simplex*, to be conserved
54
55
56
57
58
59
60

1
2
3 687 with a new (fossil) type (Art. 14.9) and instated as fossil-taxa along with the remaining
4
5 688 seven fossil-species, given that all eight species have always been treated as such.
6
7 689 However, molecular phylogenetic studies show that *Protopteridinium conicoides*, which
8
9 690 includes the holotype species *Brigantedinium simplex*, is basal to the Pyriforma clade of
10
11 691 *Protopteridinium* (Fig. 2) and is separated from other non-fossil species related to
12
13 692 *Brigantedinium* (*Protopteridinium abei*, *P. avellana*, *P. denticulatum*, *P. pentagonum*, and
14
15 693 *P. punctulatum*) (fig. 75 in Gu et al. 2015; fig. 1 in Gurdebeke et al. 2020; Fig. 4).
16
17 694 Accordingly, the genus *Brigantedinium* is polyphyletic. Moreover, *Brigantedinium*
18
19 695 *simplex* has two ventral depressions representing flagellar scars and may have slightly
20
21 696 raised cingular margins (Rochon et al. 1999) whereas all other species of the genus lack
22
23 697 expressions of tabulation other than the archeopyle. *Brigantedinium simplex* is
24
25 698 accordingly a morphological as well as phylogenetic outlier.

26
27
28
29
30
31 699 Conserving *Brigantedinium* in a manner allowing it to accommodate the eight
32
33 700 species presently assigned to it would compare with the fossil-genus *Spiniferites* which,
34
35 701 probably along with *Selenopemphix* (see above), is also known to be polyphyletic.
36
37 702 Alternatively, *Brigantedinium* could be conserved against *Protopteridinium* with a new
38
39 703 (fossil) type, and restricted to the holotype species *Brigantedinium simplex*, with other
40
41 704 species transferred to one or more newly created fossil-defined genera. Instead, we
42
43 705 recommend that *Brigantedinium simplex* be redefined with a fossil type and transferred to
44
45 706 a new fossil-genus, with the name *Brigantedinium* conserved using, as a new (fossil)
46
47 707 type, a holotype of one of the other species of *Brigantedinium*, such as *Brigantedinium*
48
49 708 *cariacoense*. This would allow *Brigantedinium* and all its fossil-species to continue being
50
51 709 used as they are presently, except for *Brigantedinium simplex* which, as a morphological
52
53
54
55
56
57
58
59
60

1
2
3 710 and phylogenetic outlier, would appropriately be transferred to a new fossil-genus. In
4
5 711 practical terms, most *Brigantedinium* species are distinguished from one another
6
7 712 primarily by the archeopyle shape, which is often obscured in palynological preparations;
8
9 713 except for *Brigantedinium simplex* which can be identified also by additional traces of
10
11 714 tabulation. The useful term *Brigantedinium* spp. would therefore be sustained.
12
13
14 715 Meanwhile, as a practical solution for routine counting, where critical details of the
15
16 716 archeopyle are often not discernible, we recommend use of the informal collective term
17
18 717 “round brown cysts” as this will include all species presently assignable to the genus
19
20 718 *Brigantedinium*.

21
22
23
24 719 The cyst-defined genus *Echinidinium* and its holotype species *Echinidinium*
25
26 720 *granulatum* were not validly published by Zonneveld (1997) because Latin diagnoses had
27
28 721 not been provided. This was necessary at the time because the holotype of *Echinidinium*
29
30 722 *granulatum* had been recovered from a sediment trap suspended in the water column and,
31
32 723 with doubtful stratigraphic relations (Art. 13.3), could not therefore be considered a fossil
33
34 724 (Head 2003). Head et al. (2001) validated both the genus *Echinidinium* and its holotype
35
36 725 species, *E. granulatum*, by providing Latin diagnoses. Eight validly published cyst-
37
38 726 defined species have been assigned to the genus *Echinidinium*, of which seven are
39
40 727 typified by specimens from ocean floor sediment and are therefore treated as fossils.
41
42 728 Hence, as with *Brigantedinium*, the genus *Echinidinium* is a widely reported non-fossil
43
44 729 cyst genus, proposed with the intention of being a fossil-genus, and to which fossil-
45
46 730 species have been assigned. Cysts of *Echinidinium granulatum* have been incubated and
47
48 731 genetic sequencing performed, allowing attribution to a species not previously described
49
50 732 and close to *Protoperidinium monovelum* (KNM unpublished data). If *Echinidinium*
51
52
53
54
55
56
57
58
59
60

1
2
3 733 *granulatum* were transferred to *Protoperidinium*, the genus *Echinidinium* would become
4
5 734 unavailable. The preferred solution would be for the names *Echinidinium* and
6
7 735 *Echinidinium granulatum* to be conserved with a new (fossil) type, protecting them from
8
9 736 competition for priority against *Protoperidinium* and any of its species. This approach
10
11 737 would cause minimal disruption because *Echinidinium* and *Echinidinium granulatum*
12
13 738 have always been treated as fossil-taxa and all other species assigned to *Echinidinium* are
14
15 739 already fossil-species.
16
17
18
19 740
20
21 741

22 742 **6.3. A fossil-genus emended to incorporate non-fossil species**

23
24 743
25
26 744 The fossil-genus *Islandinium* is typified by the holotype of *Islandinium minutum*
27
28 745 (basonym: *Multispinula? minuta* Harland and Reid in Harland et al. 1980), a cyst
29
30 746 obtained from modern sediments of the Beaufort Sea (Harland et al. 1980) and which can
31
32 747 therefore be treated as a fossil. A significant characteristic of this protoperidinioidean
33
34 748 genus is the presence of a saphopylic Type A3 apical archeopyle (i.e. the full release of
35
36 749 three opercular plates).
37
38
39
40
41

42 750 Living cysts were subsequently germinated by Potvin et al. (2013), who then
43
44 751 characterized the motile stage both with respect to its morphology and SSU and LSU
45
46 752 rDNA-based molecular phylogeny. They accordingly emended the genus *Islandinium* and
47
48 753 its holotype species *Islandinium minutum* to include details of the tabulation and
49
50 754 morphology of the motile stage as well as some aspects of the cytology, and they
51
52
53 755 incorporated new details of the cyst morphology. They also transferred the motile-defined
54
55
56
57
58
59
60

1
2
3 756 non-fossil species *Protoperidinium tricingulatum*, which had been diagnosed using both
4
5 757 thecal and cyst characteristics (Kawami et al. 2009), to the genus *Islandinium*. This
6
7
8 758 decision was supported at the time by molecular phylogeny showing *Protoperidinium*
9
10 759 *tricingulatum* closely related to *Islandinium minutum* (Potvin et al. 2013). In doing so,
11
12 760 Potvin et al. (2013) emended the genus *Islandinium* to include cysts with apical
13
14 761 archeopyles that can be theropylic, as in *Protoperidinium tricingulatum*, as well as
15
16
17 762 saphopylic.

18
19 763 There are presently no extinct species assigned to *Islandinium*, but were this to
20
21 764 happen, such species would not fully satisfy the circumscription of this genus as emended
22
23
24 765 by Potvin et al. (2013) because information on the motile stage would not be known, or
25
26 766 indeed, be knowable. It is a matter of taxonomic choice whether to accept the emendation
27
28 767 of Potvin et al. (2013), although in maintaining dual nomenclature we advocate the
29
30 768 retention of *Islandinium* in its status as a fossil-genus. A proposal to erect an equivalent
31
32
33 769 non-fossil genus is in preparation.

34
35 770 A further issue exists. *Islandinium minutum* subsp. *barbatum* was established by
36
37 771 Potvin et al. (2018) to accommodate cysts that have pronounced barbs on the processes;
38
39
40 772 *Islandinium minutum* subsp. *minutum* (autonym) by default represents morphotypes with
41
42 773 smooth to minutely ornamented process surfaces. *Islandinium pacificum* was similarly
43
44 774 erected by Gurdebeke et al. (2019) for cysts with pronounced barbs on their processes,
45
46
47 775 differing only from *Islandinium minutum* subsp. *barbatum* in having a smooth rather than
48
49 776 faintly granulate central body surface. Both *Islandinium minutum* subsp. *barbatum* and
50
51 777 *Islandinium pacificum* are typified by holotypes that are empty cysts from ocean
52
53
54
55
56
57
58
59
60

1
2
3 778 sediments and so can be treated as fossils. Both are diagnosed exclusively on cyst
4
5 779 morphology.
6
7
8 780 *Islandinium minutum* subsp. *barbatum* was not successfully germinated, but
9
10 781 molecular phylogeny performed on the cysts gave results that were largely
11
12 782 indistinguishable from *Islandinium minutum* subsp. *minutum*. This supported the decision
13
14 783 to erect *barbatum* as a subspecies rather than a separate species. The theca of *Islandinium*
15
16 784 *minutum* subsp. *barbatum* would presumably therefore conform with that of *Islandinium*
17
18 785 *minutum* subsp. *minutum* as documented by Potvin et al. (2013), although this has yet to
19
20
21 786 be confirmed.

22
23
24 787 *Islandinium pacificum* was, in contrast, successfully incubated and the emergent
25
26 788 theca identified as *Protoperidinium mutsuense*. The thecal morphology of
27
28 789 *Protoperidinium mutsuense* differs from that of *Islandinium minutum* subsp. *minutum* in
29
30 790 specific details but according to Gurdebeke et al. (2019) broadly conforms to the thecal
31
32 791 morphology attributed to the genus *Islandinium* by Potvin et al. (2013). Both
33
34 792 *Protoperidinium mutsuense* and *Islandinium minutum* are assignable to the *Americanum*
35
36 793 subclade of the *Monovela* clade of the genus *Protoperidinium* (Gurdebeke et al. 2019).

37
38
39
40 794 Detailed comparative research is needed to establish whether *Islandinium*
41
42 795 *minutum* subsp. *barbatum* and *Islandinium pacificum* can be distinguished from one
43
44 796 another in routine palynological analysis. If they can, then both names stand. If they
45
46 797 cannot, but can be routinely separated from *Islandinium minutum* subsp. *minutum*, then
47
48 798 the name *Islandinium pacificum* should be used – even though *Islandinium minutum*
49
50 799 subsp. *barbatum* (Potvin et al. 2018) was published before *Islandinium pacificum*
51
52
53 800 (Gurdebeke et al. 2019), “a name has no priority outside the rank at which it is published”

1
2
3 801 (Art. 11.2). Either way, this need not affect the application of dual nomenclature,
4
5 802 although it is possible that *Islandinium pacificum* if synonymized with *Islandinium*
6
7 803 *minutum* subsp. *barbatum* will then represent two non-fossil species.

8
9
10 804 The fossil-genus *Lingulodinium* is typified by the holotype of *Lingulodinium*
11
12 805 *machaerophorum* from the Miocene of Balcombe Bay, Australia (Deflandre and Cookson
13
14 806 1955). The genus name refers to the “small tongue” (lingula) formed on the epicyst after
15
16 807 the release of precingular plates during archeopyle formation. The equivalent theca-
17
18 808 defined non-fossil species is *Gonyaulax polyedra* (Wall and Dale 1966, 1967, 1968),
19
20 809 described from the Baltic Sea off Kiel, Germany by von Stein (1883) and since restudied
21
22 810 from the type locality (Tillman et al. 2021). Dodge (1989) emended *Lingulodinium* to
23
24 811 include thecal characteristics and transferred *Gonyaulax polyedra* to it, as *Lingulodinium*
25
26 812 *polyedra*, along with another non-fossil species *Gonyaulax milneri*, as *Lingulodinium*
27
28 813 *milneri*. *Lingulodinium milneri* is not known to produce a cyst. No other non-fossil
29
30 814 species have been assigned to the genus *Lingulodinium*. Thirteen fossil-species are
31
32 815 attributed to this genus including the holotype species (Fensome et al. 2019), collectively
33
34 816 extending the genus back to the Late Cretaceous. Since most of the fossil-defined species
35
36 817 are extinct, determining whether their motile stages would have conformed to the
37
38 818 emended diagnosis given by Dodge (1989) is practically impossible. Nonetheless,
39
40 819 *Lingulodinium* is distinct from *Gonyaulax*, the holotype species of which is *Gonyaulax*
41
42 820 *spinifera*, using both morphological (Dodge 1989) and molecular phylogenetic (e.g. Orr
43
44 821 et al. 2012; Mertens et al. 2015, 2017a; Tillmann et al. 2021) criteria. The genus
45
46 822 *Lingulodinium* is accordingly now placed in the family Lingulodiniaceae whereas
47
48 823 *Gonyaulax* (as presently understood and including *Gonyaulax spinifera*) is placed in the
49
50
51
52
53
54
55
56
57
58
59
60

1
2
3 824 family Gonyaulacaceae (Zhang et al. 2020; Tillmann et al. 2021). This separation had
4
5 825 been recognized previously, although at subfamilial level, with *Lingulodinium* assigned
6
7 826 to the Cribroperidinioideae and *Gonyaulax* to the Gonyaulacoideae (Fensome et al.
8
9
10 827 1993). The solution advanced here, following a dual nomenclatural approach, is to accept
11
12 828 the emended diagnosis of Wall and Dale in Wall et al. (1973), which is restricted to cyst
13
14 829 morphology, and to establish a new non-fossil genus, *Lingulaulax* gen. nov., for
15
16
17 830 *Gonyaulax polyedra* and *Gonyaulax milneri*, which then become *Lingulaulax polyedra*
18
19 831 (von Stein 1883) comb. nov. and *Lingulaulax milneri* (Murray and Whitting 1899) comb.
20
21 832 nov., respectively (see Systematics section, below).
22
23
24 833

26 834 **6.4. A fossil-species assigned or transferred to a non-fossil genus**

28 835
29
30
31 836 There is a long history of fossil-species being placed in non-fossil genera, an early
32
33 837 example being the Cretaceous *Peridinium pyrophorum*, a name not validly published by
34
35 838 Ehrenberg (1837) but which was subsequently validated and transferred to a fossil-genus
36
37 839 as *Palaeoperidinium pyrophorum* (Table 1). Many additional examples are listed in
38
39
40 840 Fensome et al. (2019, appendix B). Two examples are discussed below.

42 841 *Tuberculodinium vancampoe* is a fossil-species described from the subsurface
43
44 842 Pleistocene of Israel (Rossignol 1962). Rossignol (1962) treated this species as a form of
45
46 843 incertae sedis and assigned it questionably to the fossil-genus *Pterospermopsis*. Wall
47
48 844 (1967) erected the fossil-genus *Tuberculodinium*, with the holotype of *Tuberculodinium*
49
50 845 *vancampoe* serving as its type. Cyst incubation experiments subsequently demonstrated
51
52
53 846 a link with the non-fossil genus *Pyrophacus* (Wall and Dale 1971). Wall and Dale (1971)

1
2
3 847 accordingly emended the genus *Pyrophacus* to include cyst morphology, and transferred
4
5 848 *Tuberculodinium vancampoae* to *Pyrophacus*, as *Pyrophacus vancampoae*, while at the
6
7
8 849 same time emending this species to incorporate the motile stage morphology. Wall and
9
10 850 Dale (1971) had considered *Pyrophacus vancampoae* to be different from the non-fossil
11
12 851 species *Pyrophacus steinii*. However, Balech (1979) treated *Pyrophacus vancampoae* as
13
14 852 a subspecies of *Pyrophacus steinii*. It is not in fact clear whether differences exist
15
16
17 853 between the morphologies of the cysts of *Pyrophacus steinii* subsp. *steinii* and
18
19 854 *Pyrophacus steinii* subsp. *vancampoae*. Matsuoka et al. (1985a) later showed that
20
21 855 *Tuberculodinium vancampoae* is equivalent to the cyst of *Pyrophacus steinii*, a
22
23 856 judgement now generally accepted (Head 1996). Dual nomenclature offers the choice of
24
25
26 857 using either the name *Pyrophacus steinii* or *Tuberculodinium vancampoae* depending on
27
28 858 context and preference (Head et al. 2016). In addition, maintaining *Tuberculodinium*
29
30
31 859 *vancampoae* allows use of the fossil-defined genus *Tuberculodinium* which presently
32
33 860 contains four fossil-species. Furthermore, the genera *Pyrophacus* and *Tuberculodinium*
34
35 861 overlap but are not identical. *Pyrophacus horologium*, the holotype species of
36
37 862 *Pyrophacus*, produces a non-tuberculate cyst that cannot be assigned to *Tuberculodinium*
38
39 863 and may indeed be the motile stage of the fossil-species *Desotodinium wrennii* from the
40
41
42 864 Pliocene of Belgium (De Schepper et al. 2004). Dual nomenclature keeps these
43
44 865 distinctive fossil-genera available.

46
47 866 *Peridinium ponticum* is typified by an empty cyst recovered at a depth of 6–7 cm
48
49 867 in sediment core 1451G from the Black Sea (Wall and Dale in Wall et al. 1973). The
50
51 868 protologue is restricted to the cyst morphology, no motile stage then being known for this
52
53
54 869 species. No Latin diagnosis was provided by Wall and Dale but this was not needed for a
55
56
57
58
59
60

1
2
3 870 fossil algal species (Art. 44.1). The holotype is therefore treated as a fossil. The
4
5 871 assignment of this species to the non-fossil genus *Peridinium* was not directly explained
6
7 872 by Wall and Dale but presumably relates to a general similarity with the cysts of
8
9
10 873 *Proto-peridinium claudicans* as discussed by Wall and Dale (in Wall et al. 1973). The
11
12 874 combination “*Proto-peridinium ponticum*” by Matsuoka (1985b) was not validly
13
14 875 published because the basionym was not fully referenced (Fensome et al. 2019); the name
15
16
17 876 in any case is now occupied by the different species *Proto-peridinium ponticum*. The
18
19 877 motile equivalent of *Peridinium ponticum* has been identified as *Proto-peridinium cf.*
20
21 878 *divergens* by Dale (1983) although no genetic sequences are available to offer further
22
23 879 insights. The appropriate dual-nomenclatural solution would be to erect a new fossil-
24
25 880 defined genus for this species, although its variable ornamentation and especially an
26
27
28 881 outline that varies between pentagonal and subspherical (Wall et al. 1973; Mudie et al.
29
30 882 2017) would need to be considered.

31 883

32 884 **6.5. A non-fossil theca-defined species assigned to a fossil-defined genus**

33 885

34
35 886 *Proto-peridinium stellatum* was described, as *Peridinium stellatum*, from the plankton at
36
37 887 Woods Hole, Massachusetts, U.S.A. (Wall in Wall and Dale 1968). A preserved motile
38
39 888 stage was chosen as the holotype (Wall in Wall and Dale 1968, pl. 3, fig. 16), this
40
41
42 889 specimen having been incubated from a cyst collected from this plankton. The diagnosis
43
44 890 is based on the morphology of both the cyst and the incubated motile stage. Bradford
45
46 891 (1975) subsequently described the fossil-genus *Stelladinium* for species conforming to
47
48 892 the general morphology of the cysts of *Proto-peridinium stellatum*. He established

1
2
3 893 *Stelladinium reidii* as the holotype species, considering it to represent the cyst of
4
5 894 *Protoperidinium stellatum*. Reid (1977) did not accept this equivalence, a judgement
6
7
8 895 since followed by others (Head et al. 2020). He accordingly attempted to transfer
9
10 896 *Protoperidinium stellatum* (as *Peridinium stellatum*) to the genus *Stelladinium*, as
11
12 897 “*Stelladinium stellatum*” (Reid 1977), but failed to cite the basionym fully because he
13
14 898 excluded the holotype (a motile stage). Had the transfer been validly published, the non-
15
16 899 fossil theca-typified species *Protoperidinium stellatum* would have resided
17
18 900 uncomfortably within the fossil-defined genus *Stelladinium*. Until now, *Protoperidinium*
19
20 901 *stellatum* has remained without an equivalent fossil-species name. The erection of such a
21
22 902 name based on an equivalent cyst is in progress (MJH and KNM in prep.).
23
24
25

26 903

27 904

28 905 **7. Systematics**

29 906

30
31 907 We use modified Kofoidian plate labelling which includes the identification of plate
32
33 908 homologues as indicated by an asterisk (Bujak 1980; Fensome et al. 1993, text fig. 62)
34
35 909 and sulcal plate labelling following Evitt (1985).

16
17 922 **Type genus.** *Lingulodinium* Wall 1967 emend. Wall and Dale in Wall et al. 1973
18
19 923
20
21 924 **Remarks.** The family Lingulodiniaceae was established by Sarjeant and Downie (1974)
22
23 925 based on both cyst and thecal morphology, with a plate formula 3–6', 0–4a, 6'', 6C, 6''',
24
25 926 1p, 1'''' where it could be determined, and resting cysts if produced having an archeopyle
26
27 927 formed by loss of one to five precingular plates. Sarjeant and Downie (1974) included
28
29 928 two fossil-genera, *Lingulodinium* Wall 1967 and *Operculodinium* Wall 1967, and one
30
31 929 non-fossil genus, *Protoceratium* Bergh 1881. Fensome et al. (1993) considered the family
32
33 930 Lingulodiniaceae to be synonymous with and junior to the family Gonyaulacaceae
34
35 931 Lindemann 1928. Fensome et al. (1993) placed the genus *Lingulodinium* (and
36
37 932 questionably *Protoceratium* and by extension *Operculodinium*) within the
38
39 933 Gonyaulacaceae and in their new subfamily Cribroperidinioideae Fensome et al. 1993
40
41 934 which is characterized by an L-type ventral organization and dextral torsion. Zhang et al.
42
43 935 (2020) restricted the family Gonyaulacaceae to genera with an S-type ventral
44
45 936 organization, and retained and emended the family Lingulodiniaceae for genera with an
46
47 937 L-type ventral organization; a more or less symmetrical antapical outline; six or seven
48
49 938 precingular plates; when present, two or more anterior intercalary plates; and when

19 946 Genus *Lingulaulax* gen. nov.

20
21 947
22
23 948 **Type.** Pl. IV, fig. 8 of von Stein 1883, designated by Tillmann et al. (2021) as the
24
25 949 lectotype of the non-fossil species *Lingulaulax polyedra* (von Stein 1883) comb. nov.
26
27
28 950

29
30
31 951 **Status.** A non-fossil genus.
32

33 952

34
35 953 **Accepted species.**

36
37 954 *Lingulaulax polyedra* (von Stein 1883) comb. nov.

38
39 955 *Lingulaulax milneri* (Murray and Whitting 1899) comb. nov.
40
41

42 956

43
44 957 **Etymology.** A contraction of the generic names *Lingulodinium* and *Gonyaulax*, with
45
46 958 reference to the nomenclatural history of this genus.
47
48

49 959

50
51 960 **Diagnosis.** A lingulodiniacean genus in which the motile cell has no pronounced spines
52
53 961 or horns, and the plate formula APC (po, X, cp), 3', 3a, 6'', 6c, 7s, 5''' (*2'''–*6'''), 1p,
54
55
56
57
58
59
60

1
2
3 962 1'''. The 3' plate is small, and positioned along the right side of the apical pore. The
4
5 963 cingulum is offset by up to about two cingular widths, sulcus straight (L-type ventral
6
7 964 organization). Thecal plates are thick with circular depressions over the surface of the
8
9 965 plates. Cingular and sulcal lists are present. Plate 6'' is 5-sided, and plate 3' is small.
10
11 966 Torsion is dextral. Resting cysts when present have a precingular archeopyle, and if
12
13 967 processes occur, they are non-sutural in distribution. (Adapted in part from Dodge 1989,
14
15 968 p. 291).

16
17 969
18
19 970 **Remarks.** The genus *Gonyaulax* Diesing 1866 emend. Dodge 1989 differs from
20
21 971 *Lingulaulax* gen. nov. in its epicystal tabulation which is characterized by two anterior
22
23 972 intercalary plates rather than three (Dodge 1989), and an S-type ventral organization.
24
25 973 *Gonyaulax* also often has a conspicuous ventral pore between 3' and 2a (Mertens &
26
27 974 Carbonell-Moore 2018). *Amylax* Meunier 1910 differs in having a large 3' plate (Dodge
28
29 975 1989), and *Sourniaea* Gu et al. in Zhang et al. 2020 differs in having four apical and two
30
31 976 anterior intercalary plates, and smooth resting cysts with an apical archeopyle. *Sourniaea*
32
33 977 may also have pronounced antapical horns, as in the holotype species *Sourniaea*
34
35 978 *diacantha* (Gu et al. in Zhang et al. 2020).

36
37 979 Establishment of the new non-fossil genus *Lingulaulax* allows the fossil-genus
38
39 980 *Lingulodinium* to be used exclusively for fossil-species.

26 995
27

28 996 **Isotype.** SEM stub [U. Tillmann K3-G8] s.n. (CEDiT2020E108!), Tillmann et al. (2021).
29
30

31 997
32

33 998 **Description.** Motile cell heptagonal in dorsoventral outline, with margins nearly straight,
34
35 999 and nearly circular in polar outline. An obtuse angle marks the precingular and apical
36
37
38 1000 plate series contact. A small, raised apical pore complex (APC) is present on the epitheca.
39
40 1001 The hypotheca is trapezoidal in outline and has a flat antapex lacking projections. There
41
42 1002 is no dorso-ventral compression. Plate formula, APC (Po, X, cp), 3', 3a, 6'', 6c, 6s, 6'''*,
43
44 1003 1p, 1'''. The cingulum is narrow, almost median, fairly deeply incised and with narrow
45
46
47 1004 lists, descending without overlap, and offset by about two cingulum widths. The sulcus is
48
49 1005 vertical, straight, broad at the posterior and narrow towards the anterior where it just
50
51 1006 enters the epitheca, and bordered by sulcal lists. The thecal plates are thick and have
52
53
54 1007 prominent ridges along the sutures on the overlap margins. The surface of mature plates
55
56
57
58
59
60

1
2
3 1008 is coarsely areolate and includes ring-shaped ridges around the numerous trichocyst
4
5 1009 pores. Ridges connect adjacent areolae on mature plates. The first apical plate is long and
6
7 1010 narrow and has a ventral pore on its right margin. Plate 2' is heptagonal and large. Plate 3'
8
9 1011 (on the right side) is small and narrow, curving around the right-hand margin of the apical
10
11 1012 pore complex. The APC contains an elongated oval pore plate bordered by a raised rim.
12
13 1013 The centre of the pore plate contains a cover plate bearing small, elongate structures.
14
15 1014 There are three pentagonal anterior intercalary plates all of similar size situated on the
16
17 1015 right side of the epitheca. The six cingular plates are all approximately similar in size.
18
19 1016 Apart from the ms plate, sulcal plates are at least partly ornamented and porate. Plate 1'''*
20
21 1017 is small, occurs within the sulcus, and may not contact cingulum. Keystone plates are 3'',
22
23 1018 c3 and 4'''* in the precingular, cingular and postcingular series, respectively. Cell length,
24
25 1019 39–53 μm ; cell width, 34–48 μm (Adapted from Dodge 1989; Tillmann et al. 2021; Fig.
26
27 1020 5.)
28
29
30
31
32

33 1021 The resting cyst has a spherical to ovoid central body and a granulate to
34
35 1022 microrugulate surface. The archeopyle is usually precingular representing the individual
36
37 1023 release of one or more precingular plates (up to 1''–5'') but with the apical plates
38
39 1024 remaining attached to the sulcus (Wall 1967); although an epittractal archeopyle may be
40
41 1025 occasionally developed. The archeopyle margin has rounded angles. Processes are
42
43 1026 nontabular, hollow, with circular bases, and tend to flatten distally; distal ends are closed
44
45 1027 and taper to fine points or may occasionally be capitate. Processes may be slightly
46
47 1028 constricted at their base, and have smooth surfaces but may bear fine spinules along their
48
49 1029 distal third. Process length can vary considerably (0–35 μm). There are no other
50
51
52
53
54
55
56
57
58
59
60

1
2

6

7
8 1032

9
10 1033 **Remarks.** Detailed SEM observations of motile cells from the type locality in the Baltic
11
12 1034 Sea off Kiel, Germany are provided by Tillmann et al. (2021). Nehring (1994) illustrated
13
14 1035 cysts from modern sediments of the Kiel Bight.
15

16
17 1036

18
19 1037

20
21 1038 *Lingulaulax milneri* (von Stein 1883) comb. nov.
22

23
24 1039

25
26 1040 **Basionym.** *Goniodoma milneri* Murray and Whitting 1899, p. 325, pl. 27, fig. 2a–d.
27

28 1041 **Synonyms.**

29
30 1042 *Heterodinium milneri* (Murray and Whitting 1899) Kofoid 1906, p. 353.
31

32
33 1043 *Gonyaulax milneri* (Murray and Whitting 1899) Kofoid 1911, p. 203.
34

35
36 1044

37
38 1045 **Remarks.** Kofoid (1911) placed *Gonyaulax milneri* with *Gonyaulax polyedra* in his
39
40 1046 *Polyedra* group. SEM illustrations by Taylor (1976, pl. 44, figs. 517a–c) show a
41
42 1047 polyhedral outline and epithecal tabulation very similar to that of *Lingulaulax polyedra*,
43
44 1048 although the epitheca is considerably shorter than the hypotheca. In proposing this
45
46 1049 species, the authors illustrated different cells (Murray and Whitting 1899, fig. 2a–d) and
47
48 1050 did not designate a holotype (this became a requirement only on 1 January 1958; Art.
49
50 1051 40.1). Therefore, no holotype exists for this species.

1
2
3 1053
45 1054 **8. Summary and conclusions**6
7 1055
8

9
10 1056 Biological nomenclature must be flexible to reflect new phylogenetic information but
11
12 1057 also conservative to promote stability and continuity. The ICN explicitly distinguishes
13
14 1058 between fossil- and non-fossil algal taxa (diatoms excepted), recognising the fundamental
15
16 1059 differences in their underlying taxonomic concepts. Living organisms can be
17
18 1060 circumscribed potentially on the basis of their entire life history and genome, whereas
19
20 1061 fossils cannot. These concepts and this distinction form the basis for dual nomenclature.
21
22 1062 Therefore, inconsistencies and ambiguities arise when binomials are created that combine
23
24 1063 fossil with non-fossil names. In some cases, these hybridized names result from
25
26 1064 misunderstandings over the fossil or non-fossil status of these names. In examining this
27
28 1065 hybridized nomenclature and the problems it may create, solutions and courses of action
29
30 1066 have been proposed and are summarized below.

31
32 1067 *Nematosphaeropsis labyrinthus* is a commonly reported non-fossil species
33
34 1068 assigned to a fossil-genus. When its motile stage has been identified, *Nematosphaeropsis*
35
36 1069 *labyrinthus* will either require transfer to a non-fossil genus or will become a junior
37
38 1070 heterotypic synonym unless it is conserved with a new (fossil) type, as we recommend,
39
40 1071 allowing it to be used in the manner always intended for this species.

41
42 1072 The ecologically important Quaternary genus *Brigantedinium* is typified by the
43
44 1073 holotype of *Brigantedinium simplex* which is a non-fossil cyst. Incubation studies have
45
46 1074 linked *Brigantedinium simplex* to the theca-defined non-fossil species *Protoperidinium*
47
48 1075 *conicoides* which is the senior heterotypic synonym. In turn, *Brigantedinium* is a junior
49
50
51
52
53
54
55
56
57
58
59
60

1
2
3 1076 heterotypic synonym of the large non-fossil genus *Protoperidinium*. Moreover, the genus
4
5 1077 *Brigantedinium* is polyphyletic and *Brigantedinium simplex* a morphological outlier. Our
6
7 1078 preferred solution would be to conserve the name *Brigantedinium simplex* with a new
8
9 1079 (fossil) type and transfer to a new fossil-genus, and the name *Brigantedinium* conserved
10
11 1080 using as a new type the holotype of one of the fossil-species of *Brigantedinium*. With the
12
13 1081 exception of *Brigantedinium simplex*, this would allow *Brigantedinium* and all its fossil-
14
15 1082 species to continue being used as they are presently. The informal term “round brown
16
17 1083 cysts” would remain a useful collective label for all these cyst morphotypes.
18
19
20

21 1084 The cyst-defined *Echinidinium* is similarly a non-fossil genus because its type, the
22
23 1085 holotype of *Echinidinium granulatum*, is a non-fossil specimen. Incubation and genetic
24
25 1086 sequencing studies have linked *Echinidinium granulatum* to an undescribed species of
26
27 1087 *Protoperidinium*. Upon the publication of that new *Protoperidinium* species, the genus
28
29 1088 *Echinidinium* and its holotype species *Echinidinium granulatum* will become junior
30
31 1089 heterotypic synonyms unless these names are conserved with a new (fossil) type, which
32
33 1090 we recommend as it will then allow *Echinidinium* and all its species to be used as
34
35 1091 originally intended.
36
37
38
39

40 1092 Based on incubation studies, the fossil-genus *Islandinium* and its holotype species
41
42 1093 *Islandinium minutum* were emended by Potvin et al. (2013) to include characters of the
43
44 1094 motile cell. If an extinct species should be assigned to *Islandinium* an ambiguity will exist
45
46 1095 because its motile stage would be unknowable. Following the application of dual
47
48 1096 nomenclature, *Islandinium* is here treated as a fossil-genus as had been initially intended,
49
50 1097 and a proposal is being prepared to create an equivalent non-fossil genus.
51
52

53 1098 The fossil-genus *Lingulodinium* is typified by the holotype of *Lingulodinium*
54
55
56
57
58
59
60

1
2
3 1099 *machaerophorum*, an extant fossil-species from the Miocene of Australia (Deflandre and
4
5 1100 Cookson 1955). The theca-defined non-fossil species equivalent to *Lingulodinium*
6
7 1101 *machaerophorum* is *Gonyaulax polyedra*. Dodge (1989) emended *Lingulodinium* to
8
9 1102 include thecal characteristics and transferred *Gonyaulax polyedra* to it, as *Lingulodinium*
10
11 1103 *polyedra*. However, most fossil-defined species of *Lingulodinium* are extinct, their motile
12
13 1104 stage morphologies hence unknowable. The genus *Lingulodinium* is therefore returned to
14
15 1105 its fossil status and the new non-fossil genus, *Lingulaulax* gen. nov., is proposed along
16
17 1106 with the new combinations *Lingulaulax polyedra* (von Stein 1883) comb. nov. and
18
19 1107 *Lingulaulax milneri* (Murray and Whitting 1899) comb. nov., for the non-fossil
20
21 1108 *Gonyaulax polyedra* von Stein 1883 and *Gonyaulax milneri* (Murray and Whitting 1899)
22
23 1109 Kofoid 1911, respectively.

24
25 1110 *Peridinium ponticum*, a distinctive fossil-species assigned to a non-fossil genus, is
26
27 1111 reported frequently from Paratethyan Quaternary deposits from where it was first
28
29 1112 described, but also occurs along the Atlantic margin of Portugal (García-Moreiras et al.
30
31 1113 2018, 2023) and France (KNM pers. obs.). Creating a new fossil-defined genus for this
32
33 1114 species might be desirable, although the species shows considerable morphological
34
35 1115 variability that would require consideration.

36
37 1116 *Protoperidinium stellatum* is a theca-defined non-fossil species with a distinctive
38
39 1117 stellate cyst clearly conforming to the fossil-genus *Stelladinium*. Following dual
40
41 1118 nomenclature, a new fossil-species will be proposed to serve as the equivalent fossil
42
43 1119 name for *Protoperidinium stellatum* (MJH and KNM in prep.).

44
45 1120 *Gonyaulax ellegaardiae* was not validly published at the time of publication
46
47 1121 because it was typified by two illustrations. Requirements for valid publication are
48
49
50
51
52
53
54
55
56
57
58
59
60

1
2
3 1122 completed herein by designating one of these illustrations (fig. 2 in Mertens et al., 2015)
4
5 1123 as the holotype.
6

7
8 1124 In order to improve taxonomic integration between extant fossilizable cyst
9
10 1125 morphotypes and those of deeper geological time, we advocate the establishment of
11
12 1126 equivalent fossil-defined names for *all* such extant morphotypes where practicable. The
13
14 1127 application of such names will benefit from the typification of a cyst as a holotype. This
15
16 1128 exercise, illustrated by the case of *Protoperidinium stellatum* cysts (above), should take
17
18 1129 advantage of molecular as well as other phylogenetic evidence when constructing such a
19
20 1130 taxonomy. Dual nomenclature in dinoflagellates should be consistently available for
21
22 1131 those who wish to use it.

15

16 1151
17

18 1152 MARTIN J. HEAD is a professor of Earth Sciences at Brock University. His interests are
19
20

21 1153 in late Cenozoic marine palynology, and particularly the late Neogene–Quaternary record
22
23

24 1154 of dinoflagellate cysts and acritarchs and their application to paleoenvironmental
25

26 1155 reconstruction. He is also involved in formal chronostratigraphy including that of the
27
28

29 1156 Quaternary Period. He is a former president of AASP – The Palynological Society and of
30
31

32 1157 the Canadian Association of Palynologists.
33

34 1158
35

36 1159 KENNETH NEIL MERTENS is a researcher at Ifremer, LER BO, Concarneau, France.
37

38 1160 He received his Ph.D. in 2009 from Ghent University. His research interests are the
39

40 1161 taxonomy, evolution, phylogeny and biogeography of dinoflagellates, and the
41

42 1162 palaeoceanographic application of dinoflagellate cysts, particularly in the Quaternary and
43
44

45 1163 Neogene.
46

47 1164
48

49 1165 ROBERT A. FENSOME is a research scientist with the Geological Survey of Canada
50

51 1166 (GSC), part of the federal department of Natural Resources Canada, in their Atlantic
52
53

54 1167 Division at the Bedford Institute of Oceanography, Dartmouth, Nova Scotia. During his
55
56
57
58
59
60

1
2
3 1168 39-year tenure at the GSC, Rob has focussed mainly on Mesozoic and Cenozoic
4
5 1169 dinoflagellate cysts from offshore eastern Canada, but recently ventured into projects
6
7 1170 involving assemblages from north-western and Arctic Canada. While his mandate has
8
9 1171 involved primarily biostratigraphical and palaeoenvironmental studies, he also has a
10
11 1172 strong interest in dinoflagellate taxonomy and evolution, miospore taxonomy and
12
13 1173 geological outreach, co-authoring and co-editing two books for a general audience, one
14
15 1174 on the geology of Canada and one on the geology of Canada's Maritime Provinces.

10 1963 Figure 1. Phylogeny of the fossil-genera *Ataxiodinium*, *Bitectatodinium*, *Impagidinium*,

11
12 1964 *Spiniferites* and *Tectatodinium* inferred from partial large subunit (LSU) rRNA gene
13

14
15 1965 sequences using Bayesian inference. These genera have all been linked by incubation
16

17 1966 studies to the non-fossil *Gonyaulax spinifera* and *Gonyaulax polygramma* complexes,
18

19 1967 and all are paraphyletic. These genera nonetheless all include extinct species, and as
20

21 1968 presently circumscribed are needed in fossil cyst nomenclature. Branch lengths drawn to
22

23
24 1969 scale; scale bar indicates number of nucleotide substitutions per site. Numbers on
25

26 1970 branches are statistical support values to clusters on their right (left: Bayesian posterior
27

28 1971 probabilities; right: maximum likelihood (ML) bootstrap support values). Only Bayesian
29

30 1972 posterior probabilities above 0.9 and ML bootstrap support values above 50 are shown.
31

32
33 1973 An asterisk (*) indicates maximal support (BI posterior probability = 1.0, ML bootstrap
34

35 1974 support = 100). The scale bar represents inferred evolutionary distance in changes/site.
36

37

60

1
2
3 1983 *Protopteridinium subinerme* (its fossil-defined equivalent being *Selenopemphix*
4
5 1984 *nephroides*) has not yet been sequenced. The maximum likelihood (ML) bootstrap
6
7 1985 support values (ML) over 50 and Bayesian posterior probabilities (PP) over 0.7 are
8
9 1986 shown at the nodes (ML/PP), where an asterisk (*) indicates maximal support. Clades
10
11 1987 within the *Protopteridinium* sensu stricto clade are shown. The scale bar represents
12
13 1988 inferred evolutionary distance in changes/site. From fig. 3 of Mertens et al. (2017b).
14
15
16
17 1989
18
19 1990 Figure 3. Conceptual foundation for dual nomenclature. Biological species concepts
20
21 1991 potentially incorporate all aspects of the life cycle as well as genetic and other molecular
22
23 1992 information on the living organism. The species is typified by a non-fossil specimen or
24
25 1993 illustration, and a single non-fossil species name applies to all parts of the life history and
26
27 1994 may include information from genome sequencing. The paleontological species concept
28
29 1995 is, with rare exception, confined to the morphology of the fossilized resting cyst wall,
30
31 1996 although the significance of morphological attributes may be informed by independent
32
33 1997 evidence of phylogeny (e.g. molecular) where species are extant. The species is typified
34
35 1998 by a fossil specimen, and a fossil-species name is applied. Living cysts provide the
36
37 1999 overlap between these two nomenclatural systems: dual nomenclature allows both names
38
39
40
41
42 2000 *Selenopemphix nephroides* and (the cyst of) *Protopteridinium subinerme* to be used for
43
44 2001 the illustrated cyst according to context and preference. The SEM illustration of
45
46 2002 *Protopteridinium subinerme* is from Hansen and Larson (1992) and the illustration of
47
48 2003 *Selenopemphix nephroides* is from modern sediments of the Gulf of Mexico (KNM,
49
50 2004 unpublished).

2
3 2006 Figure 4. Phylogeny of the family Protoperidiniaceae based on large subunit (LSU)
4
5 2007 rDNA. Names in red boldface type are linked to cysts assignable to the cyst-defined non-
6
7 2008 fossil genus *Brigantedinium*, including the holotype species *Brigantedinium simplex*
9
10 2009 which is linked to *Protoperidinium conicoides*. Node numbers indicate bootstrap support
11
12 2010 values (1000 replicates). An asterisk (*) indicates nodes found in all replicates. From fig.
13
14 2011 1 of Gurdebeke et al. (2020).
16
17 2012

18
19 2013 Figure 5. *Lingulaulax polyedra* (von Stein 1883) comb. nov. A, B, D, E, tracings of
20
21 2014 different motile stage cells from an SEM stub (strain K3-G8 isolated from the type
22
23 2015 locality off Kiel in the Baltic Sea) which serves as the epitype (from figs. 4B, 4G, 4D,
24
25 2016 and 4H respectively in Tillmann et al. 2021); ventral, apical, dorsal, and antapical views
26
27 2017 respectively. C and F, schematic representation of C, apical pore complex and
28
29 2018 surrounding plates (from fig. 6C in Tillmann et al. 2021), and F, mid-ventral area
30
31 2019 showing details of sulcus and surrounding plates (from fig. 6D in Tillmann et al. 2021).
32
33 2020 Solid green arrows indicate plate overlap, open green arrows indicate uncertain direction
34
35 2021 of plate overlap, and the red dashed line indicates line along which plates separate during
36
37 2022 cell division (from fig. 6 in Tillmann et al. 2021). Scale bars = 10 μ m. Modified
38
39 2023 kofoidian plate labeling includes: APC = apical pore complex, vp = ventral pore, cp =
40
41 2024 cover plate, po = pore plate, X = X-plate; and the sulcal plates, as = anterior, ras = right
42
43 2025 accessory, ms = median, rs = right, ls = left, as = anterior. The first postcingular
44
45 2026 homologue (*1'') is designated as such because it lies within the sulcus and may not
46
47 2027 contact the cingular plate series.

45 * The genus *Alexandrium* was considered a junior heterotypic synonym of *Blepharocysta*

46 Ehrenberg 1873 (Elbrächter et al. 2018, 2019). However, the conservation of an epitype for

47 *Blepharocysta splendor-maris* and its genus *Blepharocysta* allows *Blepharocysta* to be

48 understood in a way that includes no currently accepted species of *Alexandrium* (Carbonell-

49 Moore 2018; Wilson 2023). We provisionally accept that *Alexandrium* was validly published

Table 12. Nomenclatural status and, where known, motile–cyst equivalence of those fossil-taxa and cyst-producing non-fossil taxa discussed in the text. A fossil–species is one in which the type is a fossil. A name-element in bold face indicates that it is based on a type that is a fossil.

| Fossil-species | Non-fossil species (c=cyst, m=motile stage) |
|--|--|
| <i>Ataxiodinium choane</i> Reid 1974 | ? <i>Gonyaulax polygramma</i> Stein 1883 |
| <i>Bitectatodinium tepikiense</i> Wilson 1973 | <u><i>Gonyaulax</i> sp. indet. (n)</u> Not <i>Gonyaulax digitale</i> (Pouchet 1883) Kofoid 1911 -(m)— |
| <u><i>Brigantedinium auranteum</i> Reid 1977</u> | Unknown |
| <u><i>Brigantedinium majusculum</i> Reid 1977</u> | <u><i>Protoperidinium sinuosum</i> Lemmermann 1905 (m)</u> |
| <u><i>Dapsilidinium pastielsii</i> (Davey and Williams 1966) Bujak et al. 1980</u> | No equivalent non-fossil name. |
| ? <i>Desotodinium wrennii</i> De Schepper et al. 2004 | <i>Pyrophacus horologium</i> Stein 1883 (m) |
| <u><i>Dubridinium caperatum</i> Reid 1977</u> | <u><i>Preperidinium meunieri</i> (Pavillard 1913) Elbrächter 1993 (m)</u> |
| <u><i>Dubridinium cassiculum</i> Reid 1977</u> | Unknown |
| <u><i>Dubridinium cavatum</i> Reid 1977</u> | <u><i>Diplopsalopsis orbicularis</i> (Paulsen 1907) Meunier 1910 (m)</u> |
| <u><i>Dubridinium ulsterum</i> Reid 1977</u> | Unknown |
| <i>Islandinium minutum</i> (Harland and Reid in Harland et al. 1980) Head et al. 2001 | Emended by Potvin et al. (2013) to include thecal characteristics. Otherwise no equivalent non-fossil name. |
| <i>Islandinium pacificum</i> Gurdebeke et al. 2019 | <i>Protoperidinium mutsuense</i> (Abé 1936) Balech 1974 (m) |
| <i>Lingulodinium machaerophorum</i> (Deflandre and Cookson 1955) Wall 1967 | <i>Lingulaulax polyedra</i> (von Stein 1883) n-gen-et comb. <u>nov.</u> (m) |
| ? <i>Nematosphaeropsis lemniscata</i> Bujak 1984 | <i>Nematosphaeropsis labyrinthus</i> (Ostenfeld 1903) Reid 1974 (c) |
| <i>Operculodinium centrocarpum</i> (Deflandre and Cookson 1955) Wall 1967 Bütschli, <u>1885 (m)</u> | <u>Unknown (n)</u> Not <i>Protoceratium reticulatum</i> (Claparède and Lachmann 1859) 1885 (m) |

No equivalent fossil name.

Protoperidinium stellatum (Wall in Wall and Dale 1968) Balech 1994 (m)

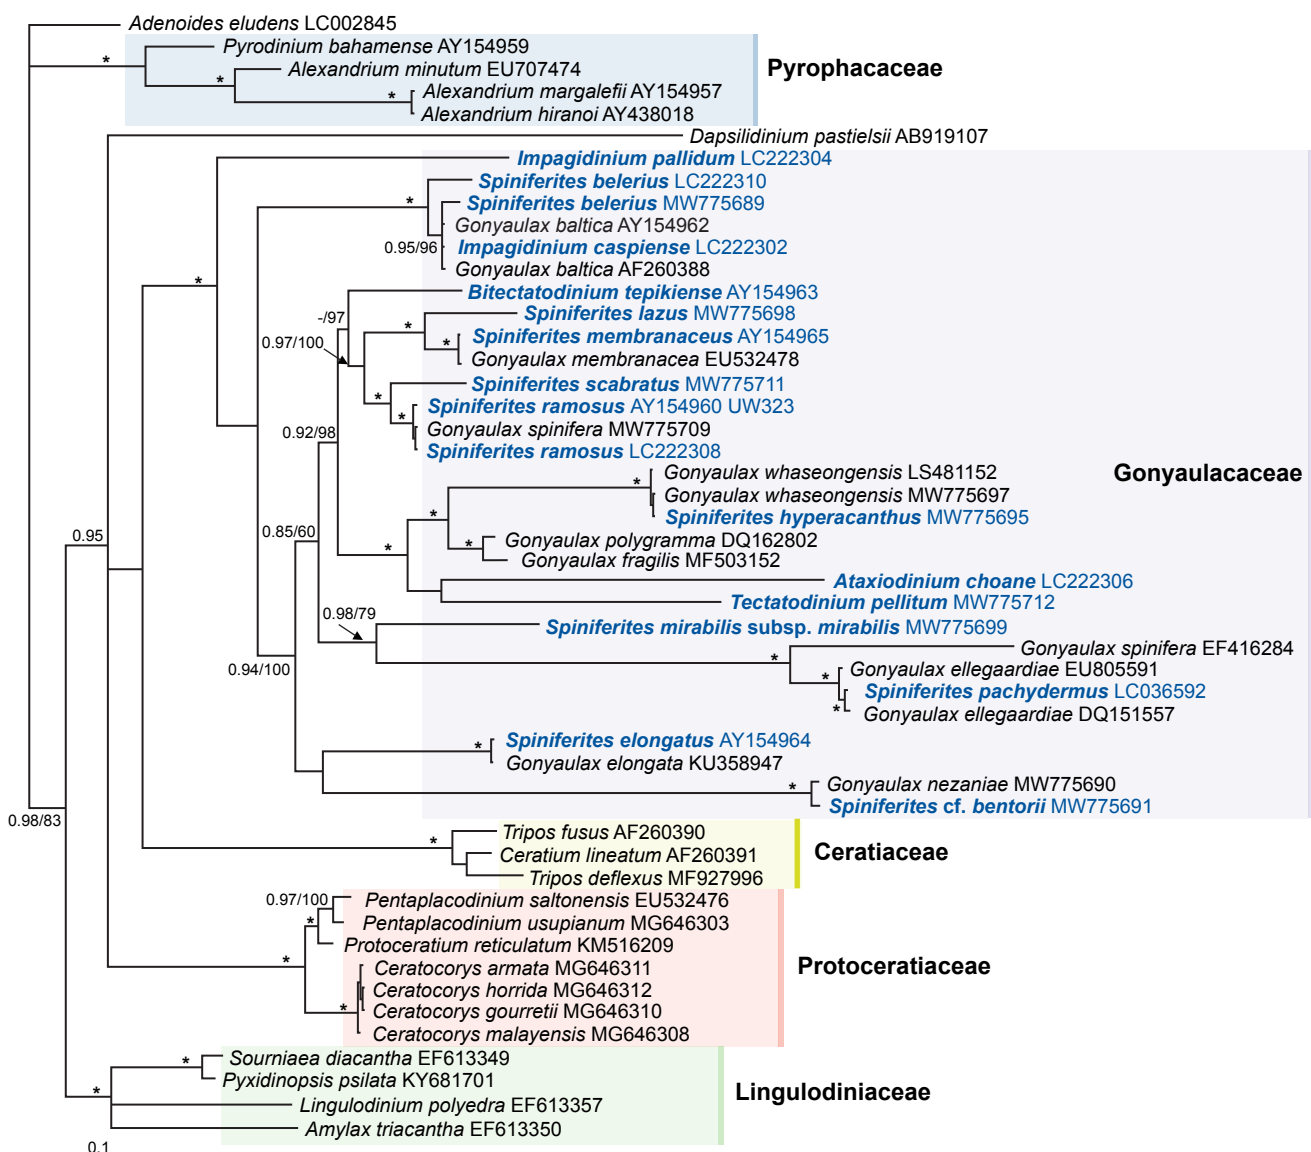

| IBC and year | Code and authors | Relevant introduction or change |
|---|---|---|
| 7 th IBC, Stockholm 1950 | Stockholm Code (Lanjouw et al. 1952) | Appendix on fossils introduced that includes “organ-genera” and “form-genera”; the term “subfossil” also introduced for which the same provisions apply as for fossils. |
| 8 th IBC, Paris 1954 | Paris Code (Lanjouw et al. 1956) | Names of non-fossil algae require illustration showing distinctive features, from 1 January 1958; and Latin description/diagnosis between 1 January 1958 and 31 December 2011. |
| 9 th IBC, Montreal 1959 | Montreal Code (Lanjouw et al. 1961) | Appendix on fossils integrated into the main body of the Code. “Organ-genera” and “form-genera” redefined as mutually exclusive concepts. |
| 10 th IBC, Edinburgh 1964 | Edinburgh Code (Lanjouw et al. 1966) | Requirement of “stratigraphic relations” at the site of original occurrence introduced for fossil taxa as a means to distinguish from “Recent material”. |
| 12 th IBC, Leningrad 1975 | Leningrad Code (Stafleu et al. 1978) | “Organ-genera” discontinued. |
| 13 th IBC, Sydney 1981 | Sydney Code (Voss et al. 1983) | Relationship clarified between “fossil” and “recent” (now lowercased) plants by referring to the latter as “non-fossil” plants. |
| 15 th IBC, Tokyo 1993 | Tokyo Code (Greuter et al. 1994) | Names of new taxa of “fossil plants” require Latin or English description or diagnosis or full and direct reference to such from 1 January 1996 (hence Latin no longer required). |
| 16 th IBC, St Louis 1999 | St Louis Code (Greuter et al. 2000) | “Morphotaxa” introduced for fossils that consist of a part, life-history stage, or preservational state. The term “fossil taxon” appears, along with first example of dual nomenclature in dinoflagellates. The type specimen of the name of a new fossil-taxon must be identified among the validating illustrations, from 1 January 2001. A type specimen of the name of an algal taxon may be a culture if metabolically inactive. |
| 17 th IBC, Vienna 2005 | Vienna Code (McNeill et al. 2006) | The type of a name of a new non-fossil taxon at the rank of species or below from 1 January 2007 must be a specimen (illustrations allowed previously for algae) except where preservation is difficult. |
| 18 th IBC, Melbourne 2011 | Melbourne Code (McNeill et al. 2012) | New title “International Code of Nomenclature for algae, fungi, and plants” (ICN) introduced. Discontinuation of terms “subfossil” and “morphotaxon”, instead distinguishing only between “fossil-taxa” and “non-fossil taxa”. Names of new non-fossil taxa require Latin or English description or diagnosis or full and direct reference to such from 1 January 2012 (hence Latin no longer required). |
| 19 th IBC, | Shenzhen Code | Simple distinction between “fossil-taxa” and “non-fossil |

Table 3. Summary of changes to the nomenclatural Codes that affect those fossil- and non-fossil algal taxa, as explained in the text, with reference to each International Botanical Congress (IBC) from 1950 and the published Code resulting from it.

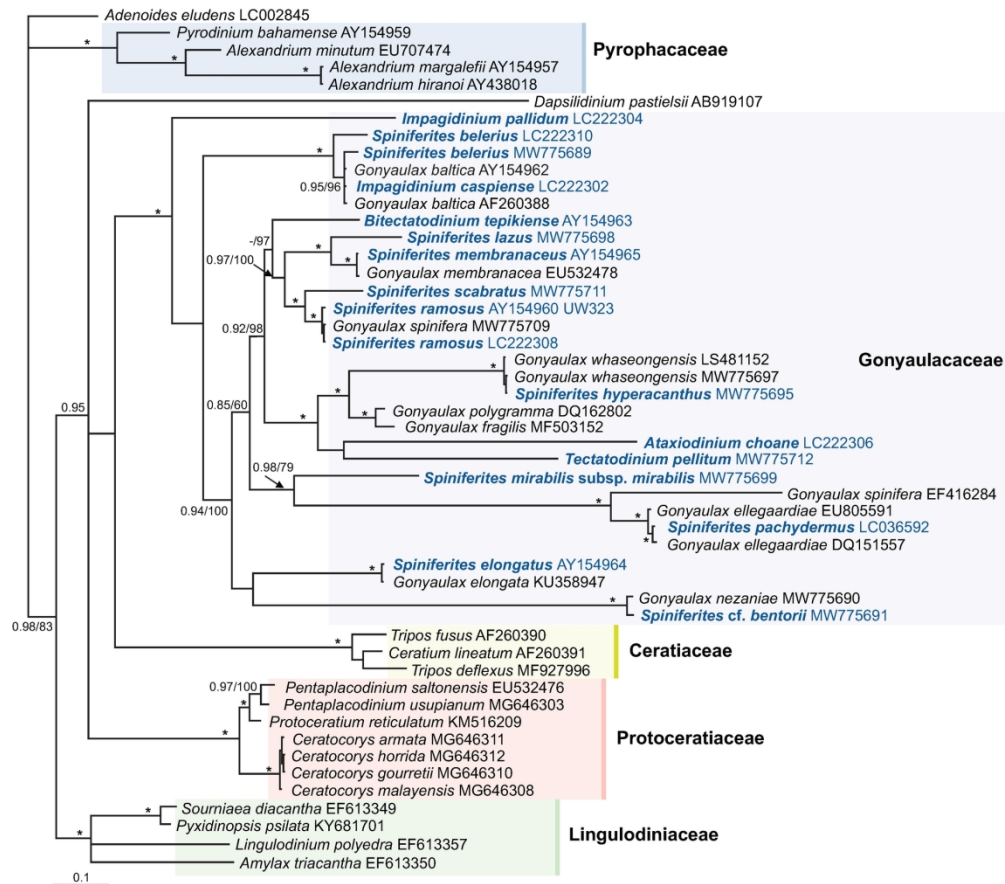

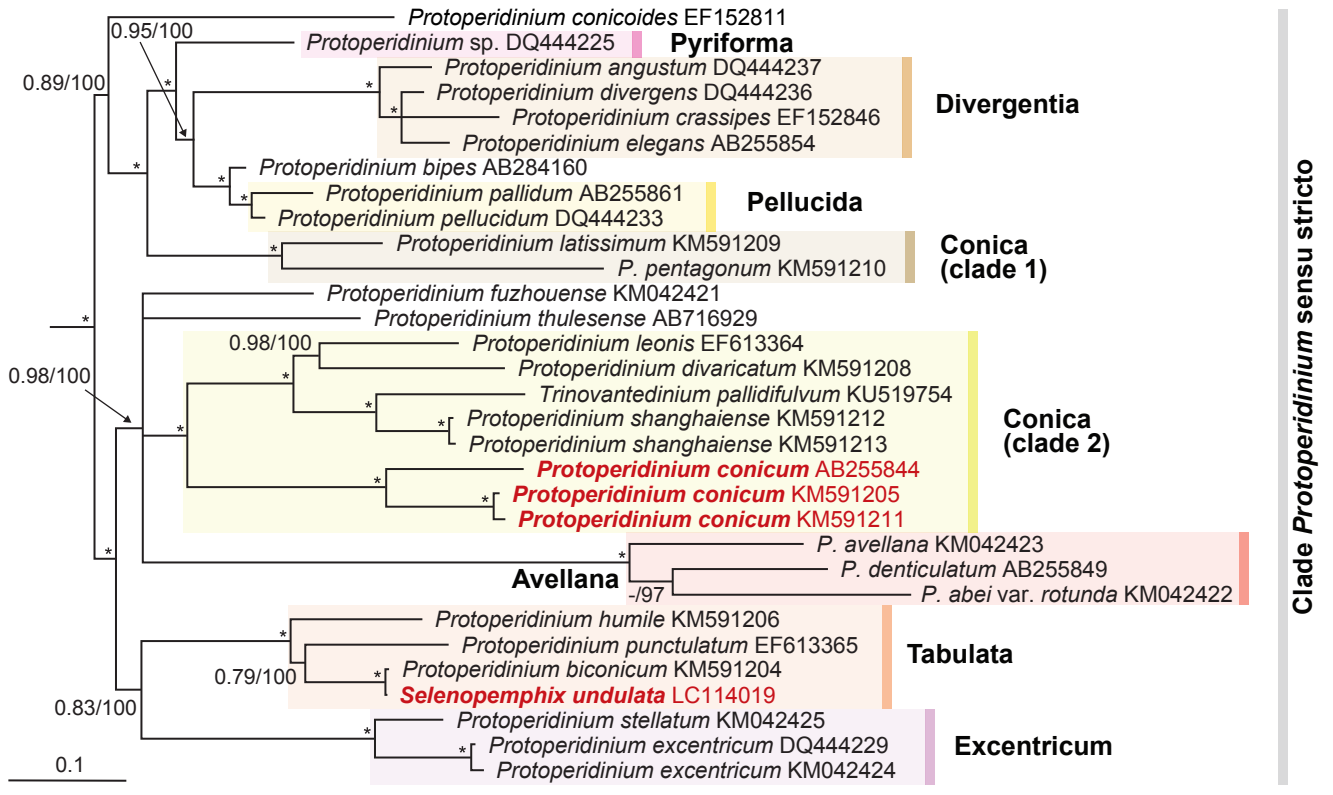

Figure 1. Phylogeny of the fossil-genera *Ataxiodinium*, *Bitectatodinium*, *Impagidinium*, *Spiniferites* and *Tectatodinium* inferred from partial large subunit (LSU) rRNA gene sequences using Bayesian inference. These genera have all been linked by incubation studies to the non-fossil *Gonyaulax spinifera* and *Gonyaulax polygramma* complexes, and all are paraphyletic. These genera nonetheless all include extinct species, and as presently circumscribed are needed in fossil cyst nomenclature. Branch lengths drawn to scale; scale bar indicates number of nucleotide substitutions per site. Numbers on branches are statistical support values to clusters on their right (left: Bayesian posterior probabilities; right: maximum likelihood (ML) bootstrap support values). Only Bayesian posterior probabilities above 0.9 and ML bootstrap support values above 50 are shown. An asterisk (*) indicates maximal support (BI posterior probability = 1.0, ML bootstrap support = 100). The scale bar represents inferred evolutionary distance in changes/site. From fig. 77 of Gu et al. (2021).

172x151mm (300 x 300 DPI)

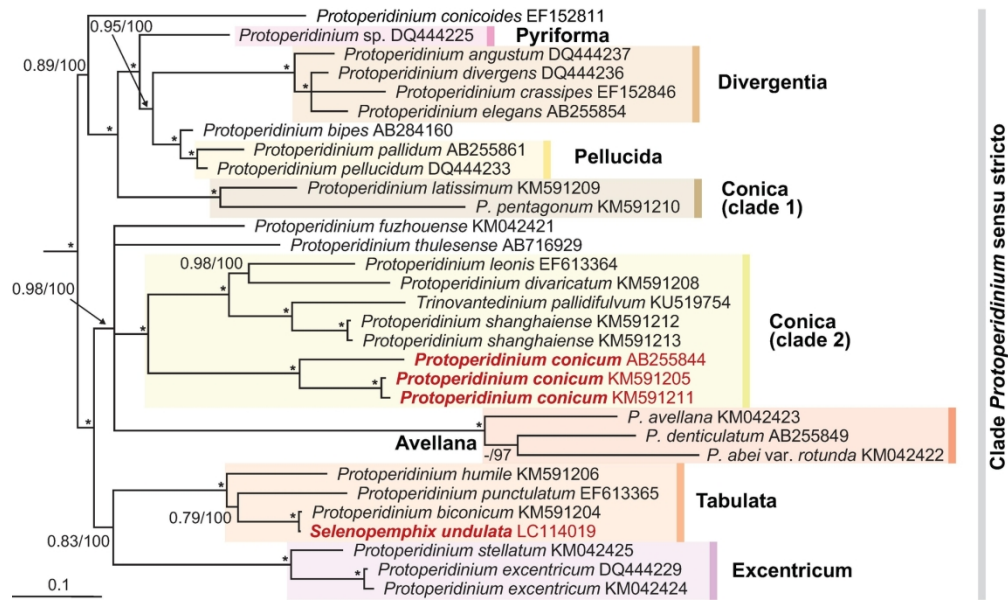

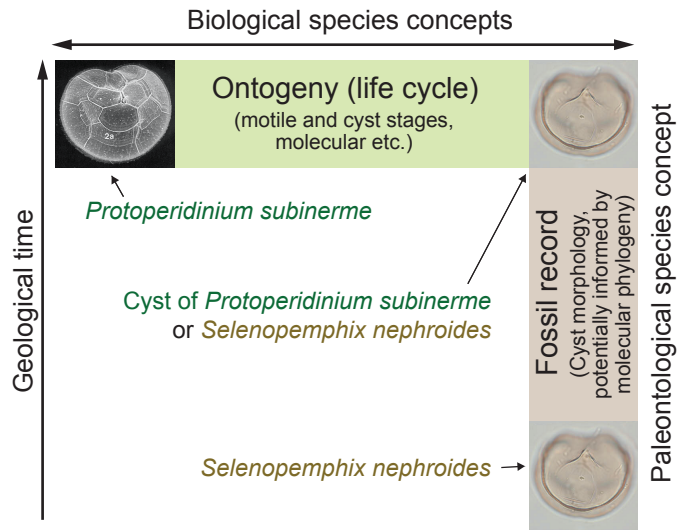

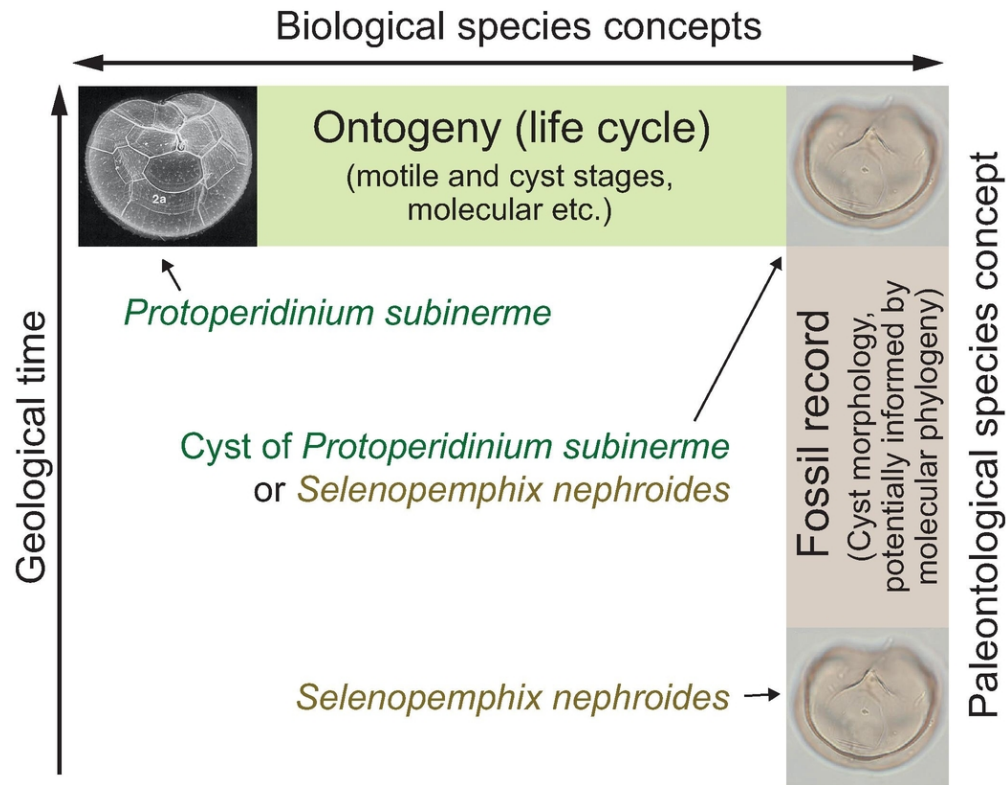

Figure 2. Phylogeny of the *Protoperidinium sensu stricto* clade inferred from LSU rRNA gene sequences using Bayesian inference, and its taxonomic implications for the fossil-genera *Selenopemphix* and *Multispinula*.

Selenopemphix undulata plots within the Tabulata clade whereas *Protoperidinium conicum*, to which *Selenopemphix* (formerly *Multispinula*) quanta has been attributed, groups within the Conica 2 clade, suggesting that *Selenopemphix* and *Multispinula* might be treated as separate fossil-genera. *Protoperidinium subinerme* (its fossil-defined equivalent being *Selenopemphix nephroides*) has not yet been sequenced. The maximum likelihood (ML) bootstrap support values (ML) over 50 and Bayesian posterior probabilities (PP) over 0.7 are shown at the nodes (ML/PP), where an asterisk (*) indicates maximal support. Clades within the *Protoperidinium sensu stricto* clade are shown. The scale bar represents inferred evolutionary distance in changes/site. From fig. 3 of Mertens et al. (2017b).

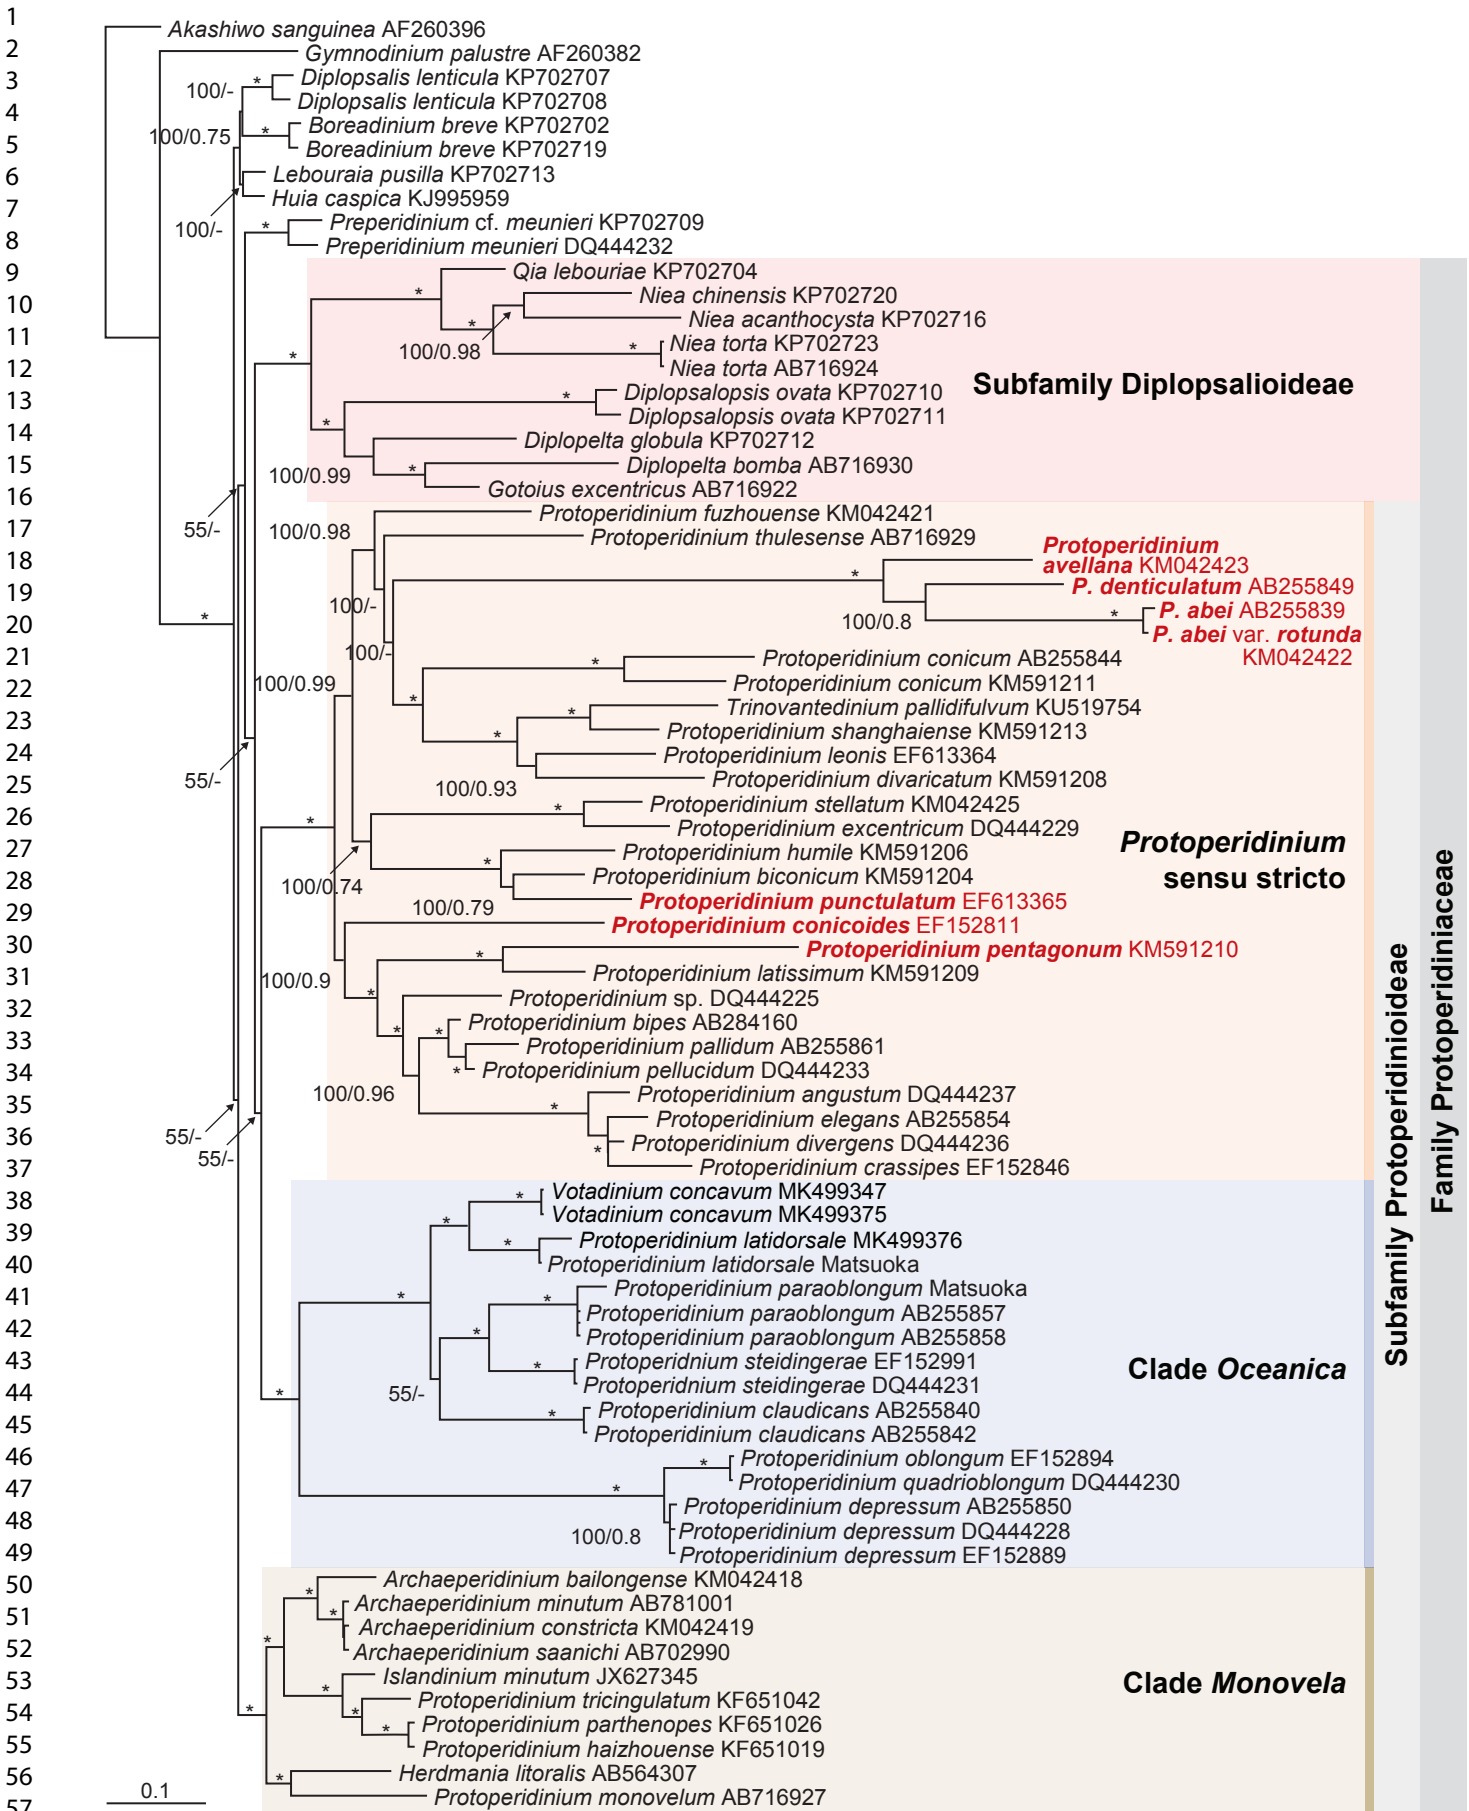

173x103mm (300 x 300 DPI)

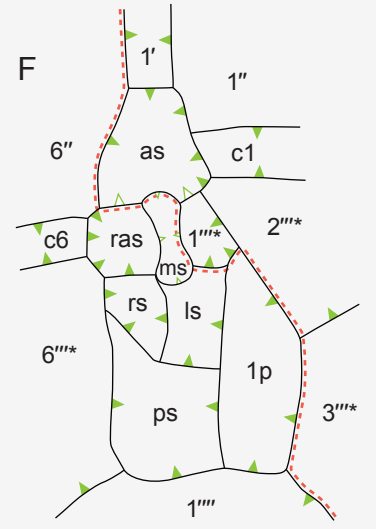

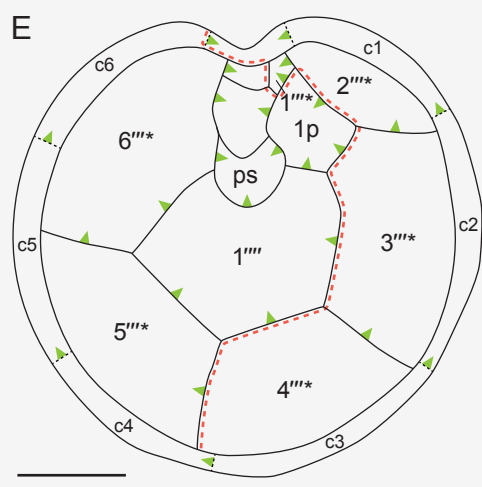

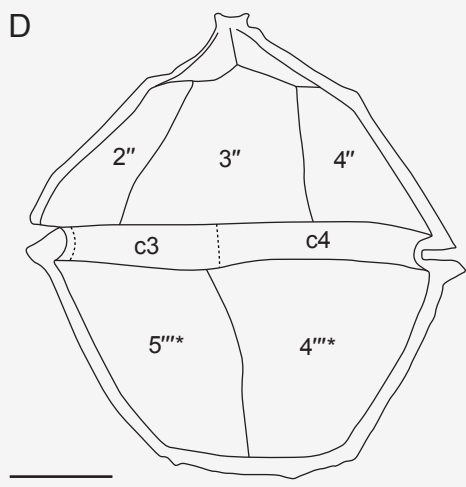

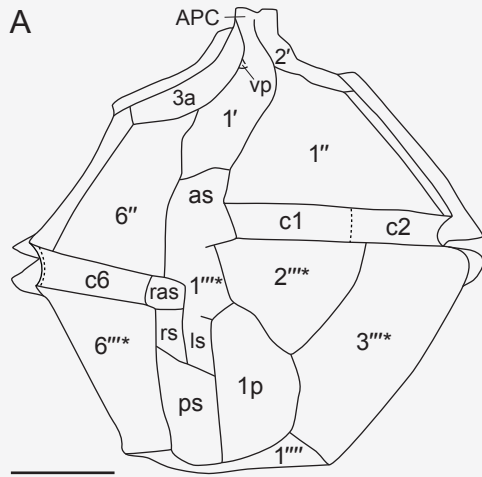

34 Figure 3. Conceptual foundation for dual nomenclature. Biological species concepts potentially incorporate all
35 aspects of the life cycle as well as genetic and other molecular information on the living organism. The
36 species is typified by a non-fossil specimen or illustration, and a single non-fossil species name applies to all
37 parts of the life history and may include information from genome sequencing. The paleontological species
38 concept is, with rare exception, confined to the morphology of the fossilized resting cyst wall, although the
39 significance of morphological attributes may be informed by independent evidence of phylogeny (e.g.
40 molecular) where species are extant. The species is typified by a fossil specimen, and a fossil-species name
41 is applied. Living cysts provide the overlap between these two nomenclatural systems: dual nomenclature
42 allows both names *Selenopemphix nephroides* and (the cyst of) *Protoperidinium subinerme* to be used for
43 the illustrated cyst according to context and preference. The SEM illustration of *Protoperidinium subinerme* is
44 from Hansen and Larson (1992) and the illustration of *Selenopemphix nephroides* is from modern sediments
45 of the Gulf of Mexico (KNM, unpublished).

45 88x74mm (300 x 300 DPI)

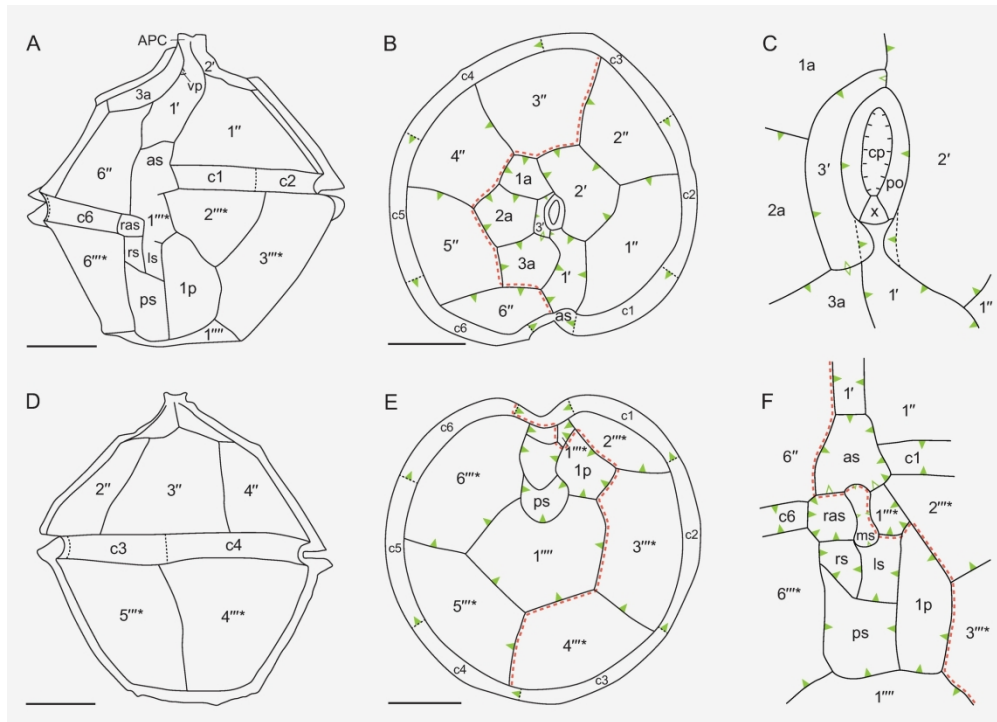

Figure 5. *Lingulaulax polyedra* (von Stein 1883) comb. nov. A, B, D, E, tracings of different motile stage cells from an SEM stub (strain K3-G8 isolated from the type locality off Kiel in the Baltic Sea) which serves as the epitype (from figs. 4B, 4G, 4D, and 4H respectively in Tillmann et al. 2021); ventral, apical, dorsal, and antapical views respectively. C and F, schematic representation of C, apical pore complex and surrounding plates (from fig. 6C in Tillmann et al. 2021), and F, mid-ventral area showing details of sulcus and surrounding plates (from fig. 6D in Tillmann et al. 2021). Solid green arrows indicate plate overlap, open green arrows indicate uncertain direction of plate overlap, and the red dashed line indicates line along which plates separate during cell division (from fig. 6 in Tillmann et al. 2021). Scale bars = 10 μ m. Modified kofoidian plate labeling includes: APC = apical pore complex, vp = ventral pore, cp = cover plate, po = pore plate, X = X-plate; and the sulcal plates, as = anterior, ras = right accessory, ms = median, rs = right, ls = left, as = anterior. The first postcingular homologue (*1''') is designated as such because it lies within the sulcus and may not contact the cingular plate series.

196x141mm (300 x 300 DPI)
