ABSTRACT

Autonomous Surface Vehicles (ASV) are becoming more affordable and include a wide variety of sensors and capacities with applications from ocean physics such as the Saildrone project to ecology with the tracking of marine species in the wild. Here, we present a multi-modal, affordable, open source, and reproducible ASV to track marine animal in shallow waters, collect information on bathymetry, and carry out photogrammetry surveys. The current specification enables scientists to track an animal equipped with an acoustic tag for 5 h and a spatial accuracy of 1 m. For bathymetric or photogrammetry surveys, the ASV can cover 100 x 100 m areas in 2 h with a distance of 1-m between transects. Depending on the sensors included in the ASV, it has a price ranging from \$2,434 to \$11,072. We illustrate these developments with a case study and a field survey for each of the different application proposed.

1 Introduction

Most of USV/ASV are very expensive and reserved for the military [Liu et al.(2016)Liu, Zhang, Yu and Yuan, Yan et al.(2010)Yan, Pang, Sun and Pang], the industry [Surfbee(2021)], or some scientific institutes [Kimball and al.(2014), Ferri et al.(2015)Ferri, Manzi, Fornai, Ciuchi and Laschi]. In the past few years, several projects emerged, proposing small and low-cost ASV/USV under \$5000 without specific sensors [Manda et al.(2015)Manda, Thein, D'Amore and Armstrong, Raber and Schill(2019), Lambert et al.(2020)Lambert, Page, Chavez and Mahmoudian]. This accessibility improvement is made thanks to

some companies proposing cheap, reliable and open-source electronics and marine robotic parts. For instance, the T200 thruster made by *Blue Robotics* is used by many hobbyists [Boat(2022)], scientists [Martorell-Torres and al.(2018)], and industrial [Surfbee(2021)] projects. We found the same evolution in software programs. Professionals and hobbyists developed good quality, easy to use, well documented, and open-source autopilots systems. For example, *Ardupilot* is now embedded in various vehicles such as drones, rovers, remotely operated vehicle (ROV) and boats [Zhao et al.(2020)Zhao, He, Li, Wang and Li, He and al.(2015), Burke(2020)]. It can also be used for data logging, analysis, and simulation. The open community linked to these projects makes them in constant and dynamic evolution.

Figure 1: Schematic of the functioning of the *Plancha* autonomous surface vehicle (ASV) and the data collected during an ASV survey: Autonomous acoustic tracking, single-beam bathymetric survey, and photogrammetric survey

In this paper, we present an ASV developed for 3 main missions:

- Autonomous acoustic tracking of a marine animal
- Bathymetric survey
- Photogrammetric survey

1.1 Autonomous acoustic tracking of a marine animal

Habitats use by marine species and their behavior can be addressed with advances in biologging technology that enable fine-scale geolocated trajectories. Biologging refers to the deployment of autonomous devices onto free-ranging animals to collect physical and biological information through its different sensors [Ropert-Coudert et al.(2012)Ropert-Coudert, Kato, Grémillet and Crenner]. A common technique for geolocated trajectory estimation of marine animals is dead-reckoning, using a fusion of inertial data, sensor speed, and GPS positions [Wilson and al.(2007)]. However, DR induce high computing effort [Gunner and al.(2021)].

Underwater fine-scale geolocated tracking is also possible with acoustic systems composed of transmitters and receivers. Some systems with anchored or buoy receivers need dense acoustic antenna arrays [Espinoza et al.(2011)Espinoza, Farrugia, Webber, Smith and Lowe] to use their geolocation algorithms. These systems are not adapted for some marine species because the distance they cover per day can be several kilometers. Some other acoustic systems are more compact, like ultra-short baseline (USBL) and short baseline (SBL) acoustic systems. USBL and SBL calculate the range of an acoustic transponder based on the signal

time of arrival (TOA) or time of flight (TOF). In addition, USBL uses a phase-differencing algorithm with the receiver baseline to get the bearing angle [Paull et al.(2014)Paull, Saeedi, Seto and Li]. With the calculated relative position, both systems infer the geolocated position of the transponder adding the global navigation satellite system (GNSS) position of the receiver system. USBL receiver systems are more compact and offer a better range and accuracy. For the Blue Print USBL ¹, the range is 1 km with 0.1 m accuracy compared to the 100 m with 1 m accuracy of the Waterlinked UGPS G2 SBL ². USBL can be installed on robotic system such autonomous underwater vehicle (AUV) [Dodge et al.(2018)Dodge, Kukulya, Burke and Baumgartner] or autonomous surface vehicle (ASV) [Page et al.(2021)Page, Lambert, Chavez-Galaviz and Mahmoudian]. Dodge et al. [Dodge et al.(2018)Dodge, Kukulya, Burke and Baumgartner] were able to follow a turtle with their AUV for several hours with an USBL. The drawbacks of the USBL systems are their prices, the transmitter size and the loss of accuracy in the shallow environment.

Here, we focus on the accurate fine scale trajectory of our future target species, a juvenile green turtles evolving in the shallow reefs of Reunion Island. We chose the SBL Waterlinked UGPS G2 system to get the underwater positions. To overcome the range constraint of 100 m, we adapted the navigation system of the ASV to follow the acoustic transponder within this range.

1.2 Bathymetric survey

Almost only professionals perform ASV bathymetry surveys, as they require expensive sensors such as an echosounder and a differential GPS for sub-centimetric positioning. The echosounder pings a signal to the bottom of the seafloor and measures the depth with the signal travel time and the signal velocity in water. For instance, it can be used to map harbors or channels. For our ecological purposes, the bathymetric map can be compared with animal depth to understand water column use during specific behaviors such as rest or feeding areas [Dodge et al.(2018)Dodge, Kukulya, Burke and Baumgartner].

In the same way as other electronic systems, bathymetric sensors tend to be cheaper. For example, we first started with an ECT-400 echosounder ³ at \$3700 and we are now testing a S-500 by Cerulean at \$595. Several projects emerged in the past few years and offered ASV for bathymetry [Kimball and al.(2014), Raber and Schill(2019), Manda et al.(2015)Manda, Thein, D'Amore and Armstrong, Carlson and al.(2019)]. These projects are not easily reproducible. For instance, the Woods Hole Oceanographic Institution *Jetyak* is not open source [Kimball and al.(2014)]. In Carlson et al. [Vlachos and al.(2019)], the bathymetry accuracy is not specified but the depth map shows pixels around 10 x 10 m. In our application, we want to be able to discriminate small seabed components with at least 5 m radius. Price also limits the use of multibeam echosounders which still cost dozens of thousands of dollars.

1.3 Photogrammetric survey

Photogrammetry enables the 3D reconstruction and mapping of a scene with overlapping images from different perspectives. Here, we propose an easy method for planning and validation of photogrammetric surveys performed with an ASV. For underwater purposes, archaeologists introduced it in 1968 [Drap(2012), Pollio(1968)]. Recently, many research teams have applied underwater photogrammetry for scientific goals [Ferrari and al.(2017), Marre and al.(2019), Million et al.(2021)Million, O'Donnell, Bartels and Kenkel]. Primarily focusing on small coral colonies with surveys made by divers, these studies give accurate coral surface estimation ranging between 2 to 19% [Lavy and al.(2015)]. Marre et al. [Marre and al.(2019)] achieved an average model resolution of 3.4 mm.

Lately, some studies have used ASV for photogrammetry surveys, but they need high computing resources and give less accurate resolution [Johnson-Roberson and al.(2010)]. Covering a larger area with an ASV is however made possible when images are coupled with accurate GPS position and orientation data. This additional information helps to run the model more quickly and accurately. Orthophotos can then be mapped on the bathymetry from the echosounder.

Software improvement simplifies the computing process without the need of long and complex pre-processing with automatic camera-ordering or camera calibration. Several softwares are available but to compare them is hard because it depends on the survey conditions and image quality [Vlachos and al.(2019)].

The drawbacks of using the ASV are the limited depth at which the bottom can be mapped, dependent on the light, image quality, turbidity, and condition at the sea surface. *Matisse*

Table 1: ASV requirements for the various operations

Global	
Handling	2 people recommended
Transport	< 2.5 m (for aircraft regulation)
Deployment	From a small boat or the shore
Environment	Tested in tropical weather: Temp : 10 – 35°C
Stance	Stable for wave : 0.5m / wind : 20 kt
Guidance	Autopilot and manual control
Buoyancy	Can support >10 kg
Communication	Telemetry range > 1 km
Power limitation	Motor under 2.5 kW
Surveys	
Lifetime per survey	>2 h
Speed	Between 0.5 and 1.2 m/s
Navigation	Autopilot allow following 1m transect
Bathymetry sensor	Single beam echo-sounder
Photogrammetry sensor	Camera (e.g. GoPro)
Communication mode	Cellular & telemetry
Tracking	
Lifetime per survey	>5 h
Speed	about 0.8 m/s
Mechanic	2 m between each hydrophone
Sensor 1	Acoustic geolocation system (SBL)
Sensor 2	Camera for behavior analysis
Communication mode	Celular & telemetry

[Arnaubec et al.(2015)Arnaubec, Opderbecke, Allais and Brignone] is one of the rare photogrammetry software available for underwater application. It is open-source and provides 3D and 2D models.

This paper describes the necessary tools to build and use an ASV with acoustic tracking ability as well as bathymetry and photogrammetry data collection.

In the first section, we describe the ASV (mechanical, electrical and software parts). The validation and characterization Section presents each functionality of the ASV with field surveys. We provide the complementary information, mounting instruction, hardware, and software files as well as training datasets in a GitLab repository ⁴.

2 ASV Description

The ASV requirements are summarized in Table 1. The hull is made from a paddleboard to be easily deployed, transportable and rugged. Depending on the deployment location, the needs and the different available resources, the ASV can be used with or without 3G/4G network. All functions are possible with or without internet although acoustic tracking is more complex without an internet connection and does not allow checking the tracking live. The global network system architecture of the ASV is detailed in Figure 4.

To be affordable and reproducible, all the electronical parts (excepted the echosounder) are commonly used components of robotics hobbyists and are easy to buy from general robotics sellers.

We divided this section into mechanical and electronic parts. In Table 2a, we presented the main components with the total price of each ASV configuration. A complete BOM ⁵ is provided. The mounting tutorials, wiring, CAO files, and installation configuration of the different software components are available on GitLab repository ⁶.

2.1 Mechanical part

The main mechanical parts are a paddleboard, a waterproof case for the electronics, and a thruster support underneath the board. Some of the custom parts are made using a 3D printer. For the acoustic mode, arms are added to hold and immerse 4 hydrophones.

(a) ASV preparation for a survey in remote mode with the mobile GPS RTK base station (on the yellow tripod)

(b) ASV in acoustic mode

Figure 2: ASV photos for the different modes: (a) Survey mode for bathymetric and photogrammetric data collection and (b) acoustic mode for animal tracking with the four arms equipped with hydrophones.

2.1.1 Hull, cases and thruster

The hull is made with a simple paddle board of 8" and 80 L. Two thrusters are used and mounted on the protection support when the board is on the ground or in very shallow waters. This support is made in 5 mm marine aluminum to be robust and is screwed to the board. We place a support base screw and bolted it on both sides to be waterproof and robust. Cables are passed through the board thanks to two printed and coated cable entries. The echosounder support is also printed and potted in a hole drilled in the board.

Table 2: Description of the main ASV parts for the different configurations and operations

(a) Different parts classified by mode and operation

Global Mode	Component	Name	Nb	Unit Price
Electrical	Fligh controller	Pixhawk cube 2.1 black	1	\$315
	GNSS RTK	Emlid reach M2	1	\$499
	Telemetry	RFD900	1	\$277
	Radio command	RadioLink AT9S	1	\$129.99
	Thruster	Blue robotic T200	2	\$179
	ESC	Blue robotic Basic ESC	2	\$27
	Battery	Tattu 14.8V 25C 4S 10000mAh	2	\$149
Remote	GNSS RTK Base	Elmid reach RS2	1	\$2199
	GNSS radio communication	Reach LoRa radio	1	\$118
Internet	4G dongle	Huawei E3372	1	\$50
	Companion board	Raspberry pi 3B+	1	\$38
Mechanical	Hull	Paddle board 8", 80L	1	\$250
	Waterproof case	HRDR waterproof case	1	\$225.20
	Thruster support	Custom aluminum support	1	\$150
	Cobalt Series Connector	Blue trail engineering Connector	2	\$67
Surveys Mode				
Electrical	Echosounder	ETC400	1	\$3850
	Camera	GoPro Hero 7	1	\$349
Mechanical	Echosounder holder	Printed custom part	1	\$20
Tracking Mode				
Electrical	SBL acoustic receiver system	Waterlinked Underwater GPS	1	\$2200
	Acoustic beacon	Waterlinked locator U1	1	\$1500
	Additional battery	Tattu 14.8V 25C 4S 10000mAh	2	\$149
Mechanical	Aluminum holding arm	Aluminum tubs	2	\$200

(b) Price estimation of the ASV for the different modes. Only indicative, it does not include cheap components and spare parts

	Global (G)	G + Surveys	G + Tracking	G + Surveys + Tracking	Remote
Total	~ \$2434	~ \$6634	~ \$6802	~ \$8672	add \$2400

Electronic parts and sensors are in a waterproof case of $54 \times 42 \times 22$ cm. The GPS antenna mast is made of aluminum and acts as a ground plane for the antenna. The echosounder is wired with the Binder 770 Bulkhead Connector and the plug from *Blue Robotics*. For the wiring of the thrusters with high electrical current, we chose cobalt series bulkhead connector and the plug from *Blue Trail Engineering*.

2.1.2 Integration of acoustic part

In our case, 4 hydrophones are needed for the acoustic system. We mount them with 2 aluminum holding arms separated by 2 m following the manufacturer recommendation (see Figure2.b). The first arm in the back of the board is composed of 5 aluminum tubes: 2 small tubes of 10 cm, 2 of 60 cm and 1 of 2 m. Connection between the 60 cm and 2 m tubes are made with stainless-steel elbow from marine hardware stores. Fixation of the arm and the board are made with stainless steel bases (on the board) and stainless steel Ts for the long tube. Bases are screwed and inserted into the board. As the space between the bases is smaller on the front, we reinforce the fixation by fixing the 2 bases on printed support which is potted on the board. To connect the 4 acoustic receivers, we used binder 770 bulkhead connectors and plugs from *Blue Robotics*. They are already mounted on the acoustic electrical.

2.2 Electrical part

For the electrical and software sections, we first described the power part and then the main components and sensors. In Figure 3B), the power is represented by a blue background and the command and sensors by a green one. The core of

this part is common for an ASV or a rover. It is composed of an autopilot (component 1), a GPS module (component 4) and communication systems (component 7). The entire electrical part, external sensors (Camera, echosounder) and the Electronic Speed Controller (ESC) for the thrusters are placed into a waterproof case (Figure 3.C). Figure 3A) represents the high level electrical diagram and a picture of the ASV electrical circuit with the annotated corresponding components.

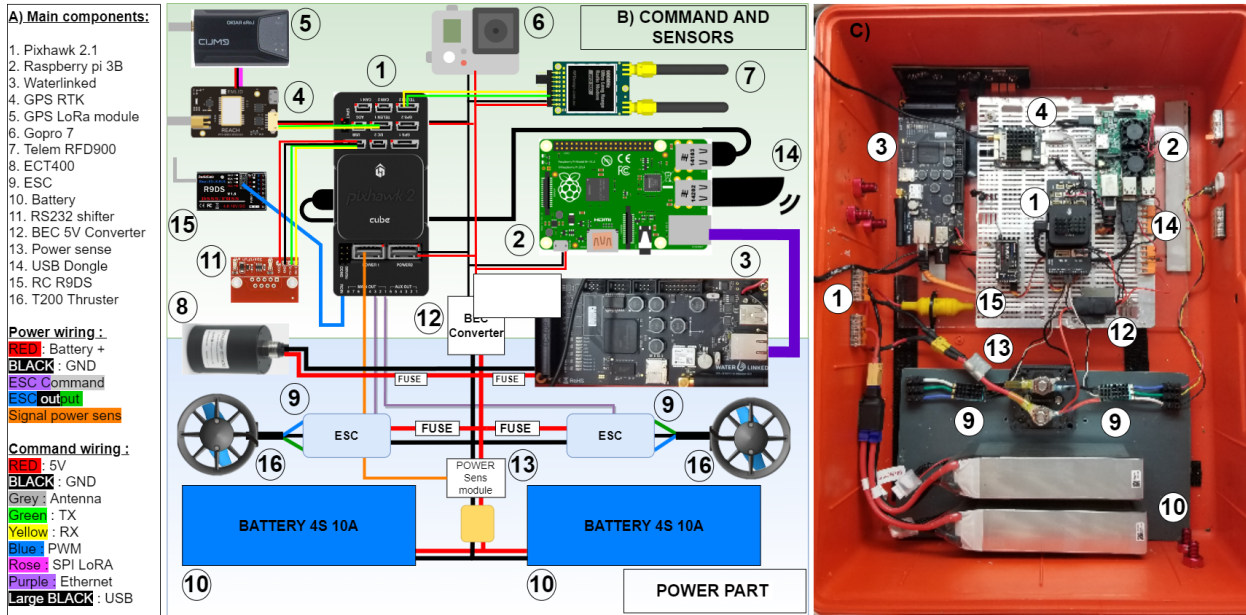

Figure 3: ASV high level electrical diagram and electrical circuit. On the left (A), the corresponding numbers and names of the main parts. The colored names correspond to different wires on the electrical diagram. In the middle (B), the high level electrical diagram with main components and wiring. On the right (C), the electrical circuit with the corresponding numbers. Some components are fixed on the top of the case or outside and thus are not visible on this photo.

2.2.1 Power part

The power part is composed of a minimum of two 4S/10Ah batteries (component 10 - Figure 3), 2 electronic speed controllers (ESC) (component 12), 2 thrusters (component 16), 1 voltage monitor (component 13), 1 voltage regulator (component 12) and some fuses. Except batteries, all the components are from *Blue Robotics*.

The following section describes the software part and how the different components communicate with each other. A graphical summary is available in Figure 4.

2.2.2 Autopilot

Autopilot or flight controller is the *Pixhawk 2.1* cube black (component 1 - Figure 3). Except the camera and SBL, all the components and sensors are connected to the flight controller. The flight controller is powered through the 5V output of the voltage regulator. The power sense module provides information on battery voltage and electrical consumption. It is also connected to the *Pixhawk*. The flight controller is configured with the open-source autopilot *Ardupilot* rover V3.5 in "boat" mode. It handles the navigation rules and the configuration of hardware and sensors. The parameters of our configuration are given in the parameter file available in the GitLab repository ⁷.

These settings depends on the board and the hardware used and a calibration should be done. The autopilot uses the mavlink protocol to communicate via USB to the companion computer and with radio telemetry to the ground-based computer. Ground control station software (GCS) is required to communicate with and control the autopilot.

⁷Parameter file path: https://gitlab.ifremer.fr/sb07899/Plancha-ASV/-/blob/main/Software/Parameters/param_110122.param

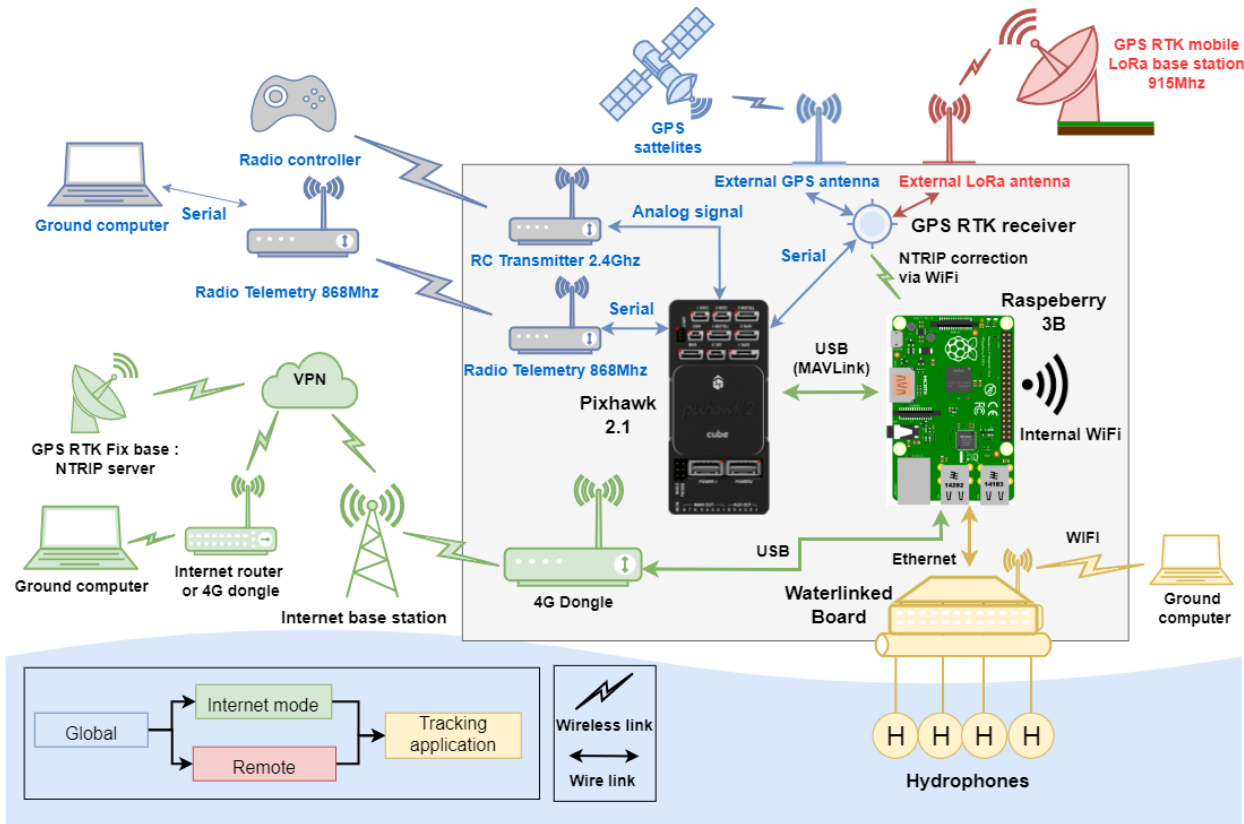

Figure 4: Network diagram of the ASV showing how the autopilot gets and interacts the difference sources of information to perform the navigation of the ASV

Different GCS are available and we used *Mission planner*. GCS displays real-time variables and positions of the ASV. Mission Planner allows mission planning for the surveys and setting all the parameters of the vehicle (Figure 5). More information on how to install and use it are available on the *Ardupilot* website⁸.

A general tutorial about *Ardupilot* rover is available on this link⁹.

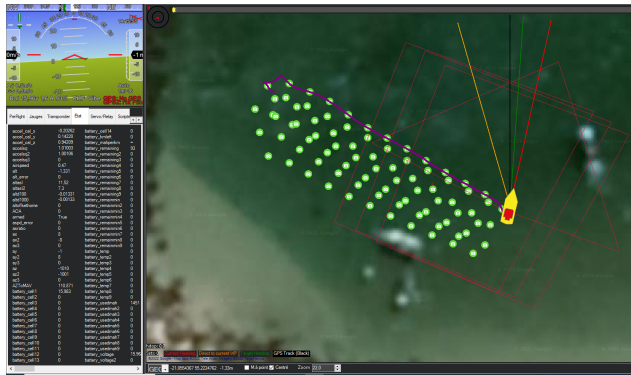

Figure 5: Screenshot of Mission Planner during a navigation test in Saint-Gilles les Bains (Reunion island). The yellow boat shape corresponds to the ASV position. Purple line is its actual track and the green dots are positions where an external signal is sent to control a camera.

⁸<https://ardupilot.org/copter/docs/common-choosing-a-ground-station.html>

⁹<https://ardupilot.org/rover/docs/rover-first-drive.html>

2.2.3 Companion computer

The companion computer is a *Raspberry Pi 3B* (component 2 - Figure 3). It is powered by a 5V voltage regulator. The companion computer and the flight controller are connected with a USB cable for serial communication. The *Raspberry Pi* has multiple roles: it communicates with the acoustic module and the flight controller and allows running custom scripts used for sensors and ASV components. During tracking mode, we run the *Python* acoustic tracking script on the *Raspberry Pi* which uses information from the flight controller and the acoustic modem. In internet mode, the connection is made using a USB 4G dongle. The companion computer then acts as a WiFi access point to share its connection. We set up and used a VPN with OpenVPN to be able to access the *Raspberry Pi* with SSH via the internet. For more information on the *Raspberry Pi* used as companion computer are available¹⁰. Detailed information and procedure to install the *Raspberry Pi* image are available on the GitHub repository¹¹.

2.2.4 RTK GNSS

We use a *Emlid Reach M2*¹² as a differential GNSS (component 4) with the possibility of Real Time Kinematics (RTK) (Figure 3). Connection is made through serial communication with a telemetry port of the flight controller. We power the *ReachM2* with the micro USB connector connected to a 5V voltage regulator. A WebGui or a smartphone app is available to configure the *ReachM2*. In internet mode, the GNSS is connected to the WiFi access point of the companion computer and corrections are fetched through an online NTRIP server (for instance using a docker available here¹³). For remote mode, corrections are fetched using a LoRa link. In that case, a second GNSS receiver is set as a reference base and sends RTK corrections to the embedded GNSS. For that purpose, we used an *Emlid RS2* at a known position. The global setup of the GNSS module is available on emlid documentation¹⁴.

2.2.5 Communication

Different methods of communication are possible. For telemetry, we used a radio or internet connection. Even for the internet mode, we used radio telemetry as backup because this system is trustworthy. The Radio telemetry (component 7 - Figure 3) allows for communication with the autopilot through ground station software via mavlink protocol. We chose the RFD900x module at 868 MHz which has a range of 20 km. It ensures a reliable link with the ASV and it is used in both modes.

To control the board in manual mode and do some simple tasks such as arming/disarming the thrusters, we used an RC command using radio communication (RC model R9DS with radiofrequency at 2.4 GHz). The RC receiver is connected to the RCIN port of the flight controller. The RC radio command (component 15 - Figure 3) is used to arm, disarm, and change mode. It is also used as a backup in case the other transmission systems fail.

2.3 Additional Sensors

2.3.1 Echosounder

The echosounder is the ECT400 by *Echollogger*¹⁵ (component (8)). It is a single beam frequency echosounder allowing bathymetry survey up to 50 m with a 5° beam. Its ground and power wires are connected to the output of the battery since its allowed power voltage spans from 8 to 75 VDC and thus does not require any voltage regulation. The echosounder communicates by serial link with the flight controller. A RS232 level shifter is used to convert the output of the echosounder to a 5 V serial signal. Depth is stored in the ardupilot log as "DPTH" variable. It needs to be configured as described in the *Ardupilot* tutorial¹⁶.

¹⁵<https://www.echollogger.com/products/single-frequency-echosounder-deep>

¹⁶<https://ardupilot.org/copter/docs/common-echollogger-ect400.html>:Configuringthesensor

2.3.2 SBL acoustic positioning

The SBL system is the underwater GPS G2 from *Waterlinked* R100 (component (3)). It is composed of 4 acoustic receivers, a master board, and an acoustic beacon. The electrical board is connected to the *Raspberry Pi* using an Ethernet cable. The input voltage range is between 10 and 30 V. We connected the board directly to the battery voltage by adding a 3 A fuse. The acoustic transmitter is the locator U1¹⁷. It works after manual activation and has 10 h lifetime. The SBL system has a 100 m of range in the standard version. The accuracy of the position given by the constructor is 1% of the range, i.e., 1 m for this application. A WebGui is available to configure the underwater GPS. The acoustic receiver array needs a specific baseline configuration.

Waterlinked recommends a distance of 2 m between each receiver. Distances between the acoustic receivers are measured on the paddleboard and set in the baseline configuration tab using the WebGui. For our application, orientation and position are fetched from the flight controller and sent by the companion computer. The settings "tab/top-side", GPS and compass have to be switched to *External*. To record the tracking, we used a custom *Python* script run from the companion computer. The software and system integration information are explained in the documentation. For our specific application, the procedure details are available in documentation folder¹⁸.

Position of the acoustic transmitter to the ASV is calculated with a signal Time of Arrival (TOA) algorithm between each different receiver. Then, the system needs the GPS position and heading of the ASV to calculate the geolocated position. To keep the acoustic transponder within the 100 m range, its position is defined as a new way point to be reached by the ASV.

2.3.3 Camera

We used the *GoPro 7* black edition (component (6)). The camera is powered by 5V from the voltage regulator. Both photogrammetry and tracking modes rely on *GoPro 7* images. For the photogrammetry the *GoPro 7* faces down, whereas in tracking mode, it has a 30° angle from the vertical position. During the photogrammetric survey, the field of view of the *GoPro 7* needs to be as linear as possible. We set the ISO parameter to the lowest value (ISO 100) and the shutter speed at a high value to get clear images and the *GoPro 7* is set in video mode. A minimum of 70% of coverage is required between two pictures for photogrammetry. To set the space between transects, we used an excel file¹⁹ calculating this space as a function of the depth of the survey area and the coverage needed. The distance between transects will also highly depend on the navigation accuracy capabilities. More information on the photogrammetric mission planning and pre-processing are available in the "prototype and survey results" Section and on the Github repository²⁰.

3 Prototype validation and survey results

To illustrate the potential applications of the ASV, we present some survey results. The validation of the ASV (e.g. accuracy of the trajectory) and the power consumption estimates are provided as Supplementary Materials. All the data and software presented in the section are fully available here²¹.

3.1 Autonomous acoustic tracking

The acoustic tracking feature allows us to get a fine scale live trajectory and an active tracking of the underwater acoustic beacon (U1 Locator). For ethical reason, we did not test and deploy the U1 Locator on a marine turtle which is a protected species although it is the target species for our application. We deployed the beacon on a freediver who was asked to mimic turtle diving behavior. The survey is carried out at Cap Lahoussaye (-21.017348°N, 55.238212°E). The locator U1 was fixed on a diver's chest with a 50 cm offset from his body towards the seabed so the locator is still underwater when the diver is at the surface and to avoid any loss of the acoustic signal. It is noteworthy that even with this 50 cm offset, we denote more spikes or signal losses when the diver is at the surface. We set the navigation rules to update the distance between the ASV and the diver every second and lower than 5 m.

¹⁸Documentation folder : https://gitlab.ifremer.fr/sb07899/Plancha-ASV/-/blob/main/Documents/2_software_instructions.docx

¹⁹https://github.com/pierreogge/Plancha-ASV/blob/main/Sotfware/Photogrammetry/Spacing_between_transect_calculator.xlsx

²¹Illustration examples link : https://gitlab.ifremer.fr/sb07899/Plancha-ASV/-/tree/main/Features_example

The acoustic tracking feature propose here can be used for other applications such as tracking AUV or any other animals with a limited swimming speed. The next subsections present the tracking procedure, the data processing, and the results of the survey example.

Figure 6: ASV tracking of a freediver. Green track is the underwater acoustic position. Red is the ASV position

3.1.1 Protocol

The *WaterLinked* system does not save the trajectory and only displays it on their WebGui. In their github²², *WaterLinked* gives example scripts in *Python* to use or save the data that can be run directly from a laptop. For tracking and logging, we developed our own logging scripts²³.

The tracking algorithm²⁴ enables the calculation of waypoints and their transfer to the autopilot. To start the tracking mode, the user needs to run the command on the *Raspberry Pi* (see software instruction). For the calculation of the next waypoint, the algorithm works as follows: Position and heading are read from the Flight controller of the ASV. It is then sent to the SBL module to calculate the position of the acoustic beacon. The Raspberry then sends a request for the position of the acoustic tag, compares the positions and decides if the ASV needs to move. If the acoustic beacon and the ASV are too close, the autopilot switches to hold mode and stands in its position. If the beacon moves away from the board and the threshold distance is exceeded (here 5 m), then a new position is sent to the autopilot which tries to reach it. Tracking parameters are stored in the Raspberry Pi²⁵.

3.1.2 Data processing

Tracking data of the 3D position of ASV and acoustic beacon are logged in the Raspberry. A *MATLAB*© script was developed to analyze, filter, and plot the data. We filter out the position data for which the standard deviation of the position estimates are larger than 3 m. A linear interpolation is performed to filter the positions of the acoustic track.

3.1.3 Results

Figure 6 shows a 25-minute sequence over which the free-diver is successfully tracked in 3D. This example demonstrates the ability of this system (ASV + acoustic beacon) to collect precise underwater positions that can be used as reference data for animal tracking applications.

For further video analyses, the image quality highly depends on the underwater visibility and the distance to the target. Figure 7 shows that videos can only be used when the visibility is good so it enables behavioral analyses. Moreover,

²⁴Tracking script in the raspberry. File name: *main_tracking.py*

²⁵Parameter file path in the *Raspberry*: */lidocean/parameter.json* file

²⁵Processing script in git: https://gitlab.ifremer.fr/sb07899/Plancha-ASV/-/blob/main/Features_example/test_tracking_26_10_21/code/main_acoustic_tracking_20_20_21.m

when the ASV is close to the target, it stays in holding mode and drifts and it can lose the target of the camera field of view.

Figure 7: Screenshot of the GoPro 7 footage during the tracking test when the diver is going up to the surface. As the seawater is turbid, it limits the ability to use the video for further behavioural analyses.

3.2 Bathymetry survey

Information extracted from bathymetric data depends on sensor specifications, but is also strongly related to the area topology and spacing between collected points. Primary parameters such as the maximum measurement range, the sampling frequency or sensor errors have been fixed during the design phase. For each survey, an *a priori* knowledge of the sea ground topology is required to define the aimed data spatial distribution over the survey area. Knowing the average depth and type of ground (e.g. large rocks, sand rift, corals, ...) will help to adjust the spacing between points. The spacing between strips has also to be adapted to the targeted map resolution.

Several standards define and classify the *quality* of bathymetric surveys. For instance, in [Organization(2020)] (section 7.3, Table I), the *International Hydrographic Organization* proposes five categories based on the overall accuracy, the area coverage, and the types of features that can be detected to help classify the *quality* and *goals* of a survey. We use these categories to define our specifications.

The next sections present the protocol, the processing stages, and the final results for a bathymetric survey with an illustration from a survey carried in 2020 on the north shore lagoon of Europa island in the Mozambique Channel.

3.2.1 Protocol

We set up the survey to meet the requirements cited in [Organization(2020)] and described in Supplementary Materials. This enables us to reach the *order 1a* category, i.e. data in harbors, harbor approach channels, coastal areas or inland navigation channels, with a limitation to areas with less than 100 m water depth.

The area of interest was a lagoon in Europa Island. Bathymetry in this area has been estimated using hyperspectral and LiDAR data collected by the Litto3D Océan Indien project in 2019²⁶ (see section 3.2.3). From these data, the depth in the area of interest is ranging from 1 to 10 m.

From these specifications and to reach the *order 1a* bathymetry standard, the aimed survey area is a rectangle of 49 m × 115 m, with a center coordinates at -22.340984°N, 40.337634°E. The parameters to configure the ASV autopilot have been set as follow:

- 24 transects in the direction of the largest dimension (width), with a 2-m spacing.
- a target cruise speed of 1 m/s.
- a depth sampling rate of 2 Hz.

These result in a grid of 24 × 228 points over the survey zone, in which the *bathymetric pixels* have a diameter ranging from 9 cm to 90 cm for depth ranging from 1 m to 10 m. Pixels have a widthwise spacing of 0.5 m and a lengthwise spacing of 2 m.

²⁶data accessible here: <https://oceans-indien-austral.milieuamrinfance.fr/Acces-aux-Donnees/Catalogue#/metadata/6b796349-d56e-44c3-b572-d5488250637e>

3.2.2 Data processing

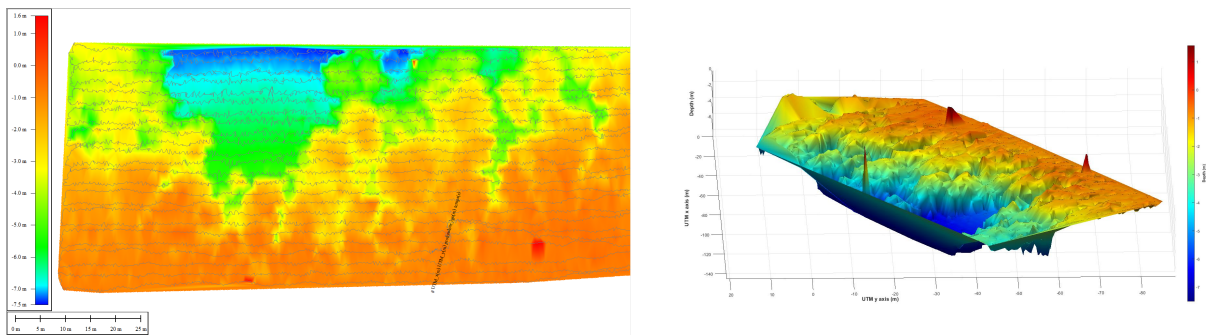

The data are retrieved from the autopilot log file which includes all information, status and measurements done by the ASV during the survey. A first step is to discard any unnecessary data to keep only the echo-sounder, GPS, and IMU data over the survey area. To achieve an accurate depiction of the seabed, a pre-processing stage is required to correct and filter the measured depths. The raw data processing includes the following steps:

- From the ASV attitude (roll, pitch, yaw) given by the IMU sensor, all points for which the pitch and roll angles are greater than a defined 10° threshold are removed.
- Using a sliding median-filter, depth values that are outside a certain range around the median depth value computed along the sliding window are removed.
- GPS data with position offsets between the GPS antenna and the location of the echo-sounder on the ASV are corrected for the 3 axis.
- Retrieve the true location of the measured depth on the sea floor by correcting the surface GPS positions with ASV attitude.
- Correct the recorded depth values with the ASV attitude, the local datum and the geoid of the survey zone, to eventually get a compensated and georeferenced depth map.

A minimal working example in *Python* is available on the git repository²⁷ associated with this article

3.2.3 Results and comparison with prior data

For the survey mentioned above, Figure 8 shows different depth estimates of the same pre-processed data set. In Figure 8(a), the depth map has been automatically computed using the *Global Mapper*® software. Overlaid gray lines represent the ASV path extracted from raw GPS data. Figure 8(b) is a 3D-projection of the same bathymetric data set build with *MATLAB*²⁸.

(a) Computed sea depth map with overlaid ASV paths (grey lines). (b) Same bathymetric data with 3D-projection and Delaunay triangulation. Plot generated with *MATLAB*

Figure 8: Bathymetry results of a survey done in 2020 in Europa Island with the ASV

To illustrate the benefits of using a single-beam echo-sounder on such ASV, we compare three different techniques that have been used to analyze the sea floor of the Europa lagoon (Figure 9). Maps are drawn for a portion of the survey area discussed before. Figure 9(a) shows the satellite imagery of the surveyed area. Figure 9(b) is a zoom on the map shown in Figure 8(a) representing the ASV bathymetry data. Figure 9(c) is the bathymetric data estimated from hyperspectral and LiDAR data collected in 2019 on the same area (Litto3D Océan Indien project).

A strict comparison of feature resolution and depth accuracy obtained with the three methods above is out-of-the-scope of this paper. Such analysis would require special attention to the different geodesic reference frames used, the level of depth correction applied, whether it includes or not environmental/experimental parameters (i.e. temperature, salinity, the effect of tides, ...), and eventually to the interpolations errors introduced by the different spatial distribution of each data set.

²⁷Example bathymetric data processing script in git : https://gitlab.ifremer.fr/sb07899/Plancha-ASV/-/blob/main/Software/Bathymetry/Compute_depth.py

²⁸Example script in git : https://gitlab.ifremer.fr/sb07899/Plancha-ASV/-/blob/main/Features_example/test_bathy_europa_09_10_20/code/main_plot_bathy_09_10_20.m

Figure 9: Three different representations of the sea floor in the survey area located inside the Europa's lagoon to compare the results from the bathymetry estimated from the ASV data to the one estimated from hyperspectral and LiDAR data

However, a qualitative analysis is enough to confirm that the ASV bathymetry gives an accurate depiction of the seabed topology in this area as compared to the satellite imagery. We observe a similar bathymetry between the ASV data and the hyperspectral/LiDAR data but with a higher level of details for the ASV bathymetry. Although aerial hyper-spectral techniques have the advantage of covering larger zones in a much shorter time, for smaller areas, deploying single-beam echo-sounders on such ASVs can be cheaper and a more practical solution with better resolution. Finally, mounting this type of echo-sounder on an ASV instead of a boat has the advantage of much regular and dense sampling patterns, as well as the opportunity to investigate areas where it is too shallow for navigation.

3.3 Photogrammetry survey

Camera images collected over the survey area can be used to obtain photogrammetry data. Here we described the protocol, the data processing, and the results for this type of surveys.

3.3.1 Protocol

To obtain the best possible results for the photogrammetry reconstruction, it is required to calibrate the camera. Indeed, to prevent lens distortion, the parameters of the lens and image sensor of the GoPro camera have to be estimated. For this calibration, multiple images of a 9 by 7 square chessboard pattern are taken in different positions and with varying angles. Camera parameters are set to full resolution. The photogrammetry software, *Matisse*, has a built-in calibration process which proposes to compute and save the camera model. We can choose between different `Distortion` models in the camera calibration settings to correspond to the fisheye distortion of the GoPro. To obtain a three-dimensional reconstruction of the survey area, it is necessary that each image must have an overlap greater than 70% with other images and photos are clear without surface effects on the seabed or ASV shadow.

Using the survey and camera information (i.e., field of view of the camera, sea depth), it is possible to define the distance between transects that approximately satisfies the first condition. We propose a tool²⁹ to estimate this distance. It does not take into account the sampling frequency of the camera and the speed of the ASV. In the example given in this paper, the speed of the vehicle is set to 0.8 m/s, the distance between transects is set to 2 m, and the depth in the studied area varies between 2 and 4 m.

3.3.2 Data processing

Underwater images suffer from various color degradation (correlated with the depth at which the image was taken, light fluctuations due to sunlight refraction etc). *Matisse* 3D carries out color and illumination corrections in a pre-processing mode. In our case, since the illumination was pretty uniform, we have checked only the `Correct colors for underwater attenuation` option while limiting the size of the images to 4 megapixels.

Once this preprocessing terminated, the reconstruction with *Matisse* 3D can be run with the post-processing mode. In order to obtain the higher reconstruction resolution, we choose the `3D Dense` algorithm.

(a) Top view reconstruction

(b) Side view reconstruction

(c) Zoom on a giant clam and on a *Pocillopora* coral

Figure 10: Different views and zooms of the photogrammetry calculated from 70 images collected by the ASV during a field survey in Europa island in 2020.

Matisse offers the possibility to use the GPS positions and orientations of the photo metadata in order to improve the result of the photogrammetry process. This piece of information is available through the ASV log but we do not use this functionality yet which need one more pre-processing step to set the metadata of the images.

3.3.3 Results

A result of a photogrammetry process on 70 images taken in Europa island is shown in Figure 10. Although the photos are all taken from the sea surface and the angle between the GoPro and the seabed remains unchanged (except for small variations due to the waves), the three-dimensional reconstruction can be performed and numerous elements characterizing the morphology of the study area can be identified (Figure 10). The geological faults are reconstructed, as well as numerous coral specimens of *Acropore Massive*, digitised and other elements such as a specimen of *Clam*.

It must be emphasized that the 3D reconstruction and the level of details is strongly correlated to the amount, position, and angle at which the photos were taken, i.e., some portions are simply not reconstructed (black areas on the image) due to a lack of images or are degraded (black spots on the side of corals).

4 Conclusion

This paper fully describes the hardware, software, and data processing tools for an autonomous surface vehicle. The ASV is able to perform:

- an autonomous navigation with an autopilot
- an autonomous acoustic tracking with an acoustic SBL system
- a bathymetric survey with a single beam echosounder for depth $< 50\text{m}$.
- a photogrammetric survey with a low-cost camera

All the components and mechanical parts are chosen to be low-cost, easy to find, and easy to build. Regarding softwares, the firmware, flight controller, and in-house development are open-source.

There are limitations to the ASV. For example, it is not designed to be used in rough sea and weather conditions. The ASV has flipped when deployed in windy conditions ($>20\text{ kt}$) and with choppy waves breaking ($\approx 0.3\text{ m}$).

In parallel to the description and the validation sections, we provide a Git repository containing all the documents, instructions, and files to reproduce this ASV. We illustrate the different features exposed for our application with dedicated field surveys. The ASV can be deployed in different environmental conditions, with or without internet. The radio telemetry system allows to control and operate the ASV with a few kilometers range. For inhabited coastal regions such as Reunion island, the ASV never loses its internet connection within the survey area ($<1\text{ km}$ from the coastline). The consumption of the ASV allows more than 4 h of survey time with two 4S batteries (10 Ah each). These batteries are compliant with air transportation regulations and makes the board easy to travel with a surf bag.

To summarize, Plancha ASV is reliable, easy to use, reproducible, and customizable. The system is small and light, and can be operated by two operators which is advised to be able to recover the board in case of an issue. With telemetry and ground control software, the ASV can be followed in real-time during the survey with a laptop. This software also offers to create survey missions, change the parameters, and calibrate the ASV. The *Ardupilot* flight controller logs the flight data and makes analyses easy with the appropriate tools.

With its high buoyancy and the space available on the board, other sensors, batteries, and other functionalities can be added. New software integration is straightforward thanks to the *Raspberry pi* as a companion computer and *Pixhawk 2.1* with *Ardupilot*.

These functions and features prove that low-cost ASV can be used for environmental and ecological purposes and provide accurate monitoring. As far as we know, this is the first time that an ASV is used to track an acoustic beacon using a low-cost SBL system. This ASV can be used to provide accurate fine-scale trajectories of underwater animals even on shallow depth and to simultaneously collect environmental information such as bathymetry and photogrammetry.
