Corrigendum to:
Paleo sea levels reconsidered from direct observation of paleoshoreline position during Glacial Maxima
(for the last 500,000 years)

In the above article, some typing errors have occurred for the values of $W_e$ and $W_s$ in Table 2. The correct Table 2 is given below with its updated Table caption (corrected values are shown in red).

\begin{table}[h]
\centering
\begin{tabular}{|c|c|}
\hline
\textbf{Value} & \textbf{Corrected Value} \\
\hline
$W_e$ & 7.5 \textcolor{red}{0.5} \\
$W_s$ & 8.0 \textcolor{red}{0.3} \\
\hline
\end{tabular}
\caption{Corrected Values for $W_e$ and $W_s$.}
\end{table}

Av. : average value between the two measurements
In the legend, the correct formula to calculate $W_m$ is $W_m=(W_e \times 0.75) + ((W_s - W_e) \times 0.8)$

We also added an uncertainty in our measurement of top shoreline depth on seismic (2ms)
Overall, final results are not changed, the uncertainty associated to the value is a little higher (2m).

Authors would like to apologize for any inconvenience caused.
### Updated Table 2

Estimate of Corrected Sea Level (CSL) from the depth of successive shorelines and subsidence corrections. Column 1: D, Erosional surface names as interpreted from seismic profiles.[60, 54]. Column 2: MIS: Marine Isotope Stage. Column 3: D (km): distance from the present day coast as measured along the profile. Column 4: $W_e$: Water-column height above shorelines (in ms twtt). Column 5: $W_s$ top shoreline depth below present sea level is measured on seismic profiles P (in milliseconds two way travel time) with an uncertainty of 2 ms. Column 6: $W_m$ Top shoreline depth below present sea level calculation in meters, considering a velocity in water $V_1=1500$ m/s and in the sediments $V_2=1600$ m/s. $W_m = (W_e \times 0.75) + ((W_s - W_e) \times 0.8)$. Av.: average value using the two measurements of $W_s$. Column 7: $b$: Paleobathymetry (m) and uncertainty associated. Column 8 and 9: RSL Relative Sea Level calculation (below present sea-level). Column 10: R: Subsidence rate that varies as a function of the tilt of the margin (from 0 m/Myr at 13 km to 250 m/Myr (+/- 10 m/Myr) at 70 km from present day coast). The rate is constant through time but varies according to the position along the profile: $R$ (m/Myr) = (D-13) * 250 / (70-13). The uncertainty reflects the uncertainty in the calculation. Column 11: A: Age of deposit is taken from dated isotope stages as defined on the SPECMAP curve and is associated with an average error of 5 kyr [73]; [80]. Column 12: S: The amount of subsidence (tilt) is calculated from subsidence rate and the age of the deposit (the associated error is related to errors on the age and on the subsidence). Corrected sea level (CSL) (column 13 and 14) is calculated from the shoreface depth $W$ (m) (column 6) minus the amount of subsidence (column 12) minus a correction for paleobathymetry estimates: $b$ (column 7).
